ABSTRACT

This document contains instructions for the installation and operation of the 4.2BSD release of the VAX* UNIX** system, as distributed by U. C. Berkeley.

It discusses procedures for installing UNIX on a new VAX, and for upgrading an existing VAX UNIX system to the new release. An explanation of how to lay out file systems on available disks, how to set up terminal lines and user accounts, and how to perform system-specific tailoring is provided. A description of how to install and configure the networking facilities included with 4.2BSD is included. Finally, the document details system operation procedures— shutdown and startup, hardware error reporting and diagnosis, file system backup procedures, resource control, performance monitoring, and procedures for recompiling and reinstalling system software.

* DEC, VAX, IDC, UNIBUS and MASSBUS are trademarks of Digital Equipment Corporation.

** UNIX is a Trademark of Bell Laboratories.

1. INTRODUCTION

This document explains how to install the 4.2BSD release of the Berkeley version of UNIX for the VAX on your system. Due to the new file system organization used in 4.2BSD, no matter what version of UNIX you may currently be running you will have to perform a full bootstrap from the distribution tape; the techniques for converting "old" systems are discussed in a chapter 3 of this document.

0.1. Hardware supported

This distribution can be booted on a VAX 11/780, VAX 11/750, or VAX 11/730 cpu with any of the following disks:

lw(1.5i) 1.

DEC MASSBUS: RM03, RM05, RM80, RP06, RP07

EMULEX MASSBUS: AMPEX 300M, 330M, CDC 300M, FUJITSU 404M

DEC UNIBUS: RK07, RA80, RA81, RA60

EMULEX SC-21V UNIBUS*:AMPEX 300M, 330M, CDC 300M, FUJITSU 160M, 404M

DEC IDC: R80, RL02

The tape drives supported by this distribution are:

lw(1.5i) 1.

DEC MASSBUS: TE16, TU45, TU77, TU78

DEC UNIBUS: TS11, TU80

EMULEX TC-11 UNIBUS: KENNEDY 9300, CIPHER

TU45 UNIBUS*: SI 9700

The tapes and disks may be on any available UNIBUS or MASSBUS adapter at any slot with the proviso that the tape device must be slave number 0 on the formatter if it is a MASSBUS tape drive.

0.2. Distribution format

The basic distribution contains the following items:

- (2) 1600bpi 2400' magnetic tapes,
- (1) TU58 console cassette, and
- (1) RX01 console floppy disk.

Installation on any machine requires a tape unit. Since certain standard VAX packages do not include a tape drive, this means one must either borrow one from another VAX system or one must be purchased separately. The console media distributed with the system are not suitable for use as the standard console media; their intended use is only for installation.

The distribution does not fit on several standard VAX configurations which contain only small disks. If your hardware configuration does not provide at least 75 Megabytes of disk space you can still install the distribution, but you will probably have to operate without source for the user level commands and, possibly, the source for the operating system. The previous RK07-only distribution format provided by our group is no longer available. Further, no attempt has ever been made to install the system on the standard VAX-11/730 hardware configuration from DEC which contains only dual RL02 disk drives (though the distribution tape may be bootstrapped on an RL11 controller and the system provides support for RL02 disk drives either on an IDC or an RL11). The labels on the two distribution tapes indicate the amount of disk space each tape file occupies, these should be used in selecting file system layouts on systems with little disk space.

* Other UNIBUS controllers and drives may be easily usable with the system, but will likely require minor modifications to the system to allow bootstrapping. The EMULEX disk and SI tape controllers, and the drives shown here are known to work as bootstrap devices.

If you have the facilities, it is a good idea immediately to copy the magnetic tapes in the distribution kit to guard against disaster. The tapes are 9-track 1600 BPI and contain some 512-byte records followed by many 10240-byte records. There are interspersed tape marks; end-of-tape is signaled by a double end-of-file.

The basic bootstrap material is present in three short files at the beginning of the bootstrap tape. The first file on the tape contains preliminary bootstrapping programs. This is followed by a binary image of a 400 kilobyte “mini root” file system. Following the mini root file is a full dump of the root file system (see *dump(8)***). Additional files on the first and second tapes contain tape archive images (see *tar(1)*): the fourth file on the first tape contains source for the system (/sys); the fifth file on the first tape contains most of the files in the file system /usr, except the source (/usr/src) which is in the first file on the second tape. The second file on the second tape contains software contributed by the user community, refer to the accompanying documentation for a description of its contents and an explanation of how it should be installed.

0.3. VAX hardware terminology

This section gives a short discussion of VAX hardware terminology to help you get your bearings.

If you have MASSBUS disks and tapes it is necessary to know the MASSBUS they are attached to, at least for the purposes of bootstrapping and system description. The MASSBUSes can have up to 8 devices attached to them. A disk counts as a device. A tape *formatter* counts as a device, and several tape drives may be attached to a formatter. If you have a separate MASSBUS adapter for a disk and one for a tape then it is conventional to put the disk as unit 0 on the MASSBUS with the lowest “TR” number, and the tape formatter as unit 0 on the next MASSBUS. On a 11/780 this would correspond to having the disk on “mba0” at “tr8” and the tape on “mba1” at “tr9”. Here the MASSBUS adapter with the lowest TR number has been called “mba0” and the one with the next lowest number is called “mba1”.

To find out the MASSBUS your tape and disk are on you can examine the cabling and the unit numbers or your site maintenance guide. Do not be fooled into thinking that the number on the front of the tape drive is a device number; it is a *slave* number, one of several possible tapes on the single tape formatter. For bootstrapping the slave number **must** be 0. The formatter unit number may be anything distinct from the other numbers on the same MASSBUS, but you must know what it is.

The MASSBUS devices are known by several different names by DEC software and by UNIX. At various times it is necessary to know both names. There is, of course, the name of the device like “RM03” or “RM80”; these are easy to remember because they are printed on the front of the device. DEC also gives devices names by the names of the driver in the system using a naming convention that reflects the interconnect topology of the machine. The first letter of such a name is a “D” for a disk, the second letter depends on the type of the drive, “DR” for RM03, RM05, and RM80’s, “DB” for RP06’s. The next letter is related to the interconnect; DEC calls the first MASSBUS adapter “A”, the second “B”, etc. Thus “DRA” is a RM drive on the first MASSBUS adapter. Finally, the name ends in a digit corresponding to the unit number for the device on the MASSBUS, i.e. “DRA0” is a disk at the first device slot on the first MASSBUS adapter and is a RM disk.

0.4. UNIX device naming

UNIX has a set of names for devices, which are different from the DEC names for the devices, viz.:

```

11.
RM/RP disks    hp
TE/TU tapes    ht
TU78 tape      mt

```

The normal standalone system, used to bootstrap the full UNIX system, uses device names:

** References of the form X(Y) mean the subsection named X in section Y of the UNIX programmer’s manual.

$xx(y,z)$

where xx is either **hp**, **ht**, or **mt**. The value y specifies the MASSBUS to use and also the device. It is computed as

$8 * mba + device$

Thus $mba0$ device 0 would have a y value of 0 while $mba1$ device 0 would have a y value of 8. The z value is interpreted differently for tapes and disks: for disks it is a disk *partition* (in the range 0-7), and for tapes it is a file number on the tape.

Each UNIX physical disk is divided into 8 logical disk partitions, each of which may occupy any consecutive cylinder range on the physical device. The cylinders occupied by the 8 partitions for each drive type are specified in section 4 of the programmers manual and in the disk description file `/etc/disktab` (c.f. `disktab(5)`).* Each partition may be used for either a raw data area such as a paging area or to store a UNIX file system. It is conventional for the first partition on a disk to be used to store a root file system, from which UNIX may be bootstrapped. The second partition is traditionally used as a paging area, and the rest of the disk is divided into spaces for additional “mounted file systems” by use of one or more additional partitions.

The third logical partition of each physical disk also has a conventional usage: it allows access to the entire physical device, including the bad sector forwarding information recorded at the end of the disk (one track plus 126 sectors). It is occasionally used to store a single large file system or to access the entire pack when making a copy of it on another. Care must be taken when using this partition to not overwrite the last few tracks and thereby clobber the bad sector information.

The disk partitions have names in the standalone system of the form “ $hp(x,y)$ ” with varying y as described above. Thus partition 1 of a RM05 on $mba0$ at drive 0 would be “ $hp(0,1)$ ”. When not running standalone, this partition would normally be available as “`/dev/hp0b`”. Here the prefix “`/dev`” is the name of the directory where all “special files” normally live, the “**hp**” serves an obvious purpose, the “0” identifies this as a partition of **hp** drive number “0” and the “**b**” identifies this as the first partition (where we number from 0, the 0th partition being “ $hp0a$ ”).

In all simple cases, a drive with unit number 0 (in its unit plug on the front of the drive) will be called unit 0 in its UNIX file name. This is not, however, strictly necessary, since the system has a level of indirection in this naming. This can be taken advantage of to make the system less dependent on the interconnect topology, and to make reconfiguration after hardware failure extremely easy. We will not discuss that now.

Returning to the discussion of the standalone system, we recall that tapes also took two integer parameters. In the normal case where the tape formatter is unit 0 on the second mba ($mba1$), the files on the tape have names “ $ht(8,0)$ ”, “ $ht(8,1)$ ”, etc. Here “file” means a tape file containing a single data stream. The distribution tapes have data structures in the tape files and though the tapes contain only 6 tape files, they contain several thousand UNIX files.

For the UNIBUS, there are also conventional names. The important DEC names to know are $DM??$ for $RK07$ drives and $DU??$ for drives on a $UDA50$. For example, $RK07$ drive 0 on a controller on the first UNIBUS on the machine is “ $DMA0$ ”. UNIX calls such a device a “**hk**” and the standalone name for the first partition of such a device is “ $hk(0,0)$ ”. If the controller were on the second UNIBUS its name would be “ $hk(8,0)$ ”. If we wished to access the first partition of a $RK07$ drive 1 on $uba0$ we would use “ $hk(1,0)$ ”.

The UNIBUS disk and tape names used by UNIX are:

* It is possible to change the partitions by changing the code for the table in the disk driver; since it is often desirable to do this it is clear that these tables should be read off each pack; they may be in a future version of the system.

11.
RK disks hk
TS tapes ts
UDA disks ra
IDC disks rb
SMD disks up
TM tapes tm
TU tapes ut

Here SMD disks are disks on an RM emulating controller on the UNIBUS, and TM tapes are tapes on a controller that emulates the DEC TM-11. TU tapes are tapes on a controller that emulates the DEC TU45. IDC disks are disks on an 11/730 Integral Disk Controller. TS tapes are tapes on a controller that emulates the DEC TS-11 (e.g. a TU80). The naming conventions for partitions in UNIBUS disks and files in UNIBUS tapes are the same as those for MASSBUS disks and tapes.

0.5. UNIX devices: block and raw

UNIX makes a distinction between “block” and “raw” (character) devices. Each disk has a block device interface where the system makes the device byte addressable and you can write a single byte in the middle of the disk. The system will read out the data from the disk sector, insert the byte you gave it and put the modified data back. The disks with the names “/dev/xx0a”, etc are block devices. There are also raw devices available. These have names like “/dev/rxx0a”, the “r” here standing for “raw”. In the bootstrap procedures we will often suggest using the raw devices, because these tend to work faster in some cases. In general, however, the block devices are used. They are where file systems are “mounted”.

You should be aware that it is sometimes important to use the character device (for efficiency) or not (because it wouldn't work, e.g. to write a single byte in the middle of a sector). Don't change the instructions by using the wrong type of device indiscriminately.

2. BOOTSTRAP PROCEDURE

This section explains the bootstrap procedure that can be used to get the kernel supplied with this tape running on your machine. Even if you are currently running UNIX you will have to do a full bootstrap.

If you are already running UNIX you should first save your existing files on magnetic tape. 4.2BSD uses a totally different file system organization than previous versions of the system; it is thus necessary to rebuild the file system format before restoring the data. The easiest way to save the current files on tape is by doing a full dump and then restoring under the new system. Refer to chapter 3 in understanding how to upgrade an existing 4BSD system.

Booting from tape

The tape bootstrap procedure used to create a working system involves the following major steps:

- 1) Format a disk pack with the *format* program.
- 2) Copy a "mini root" file system from the tape onto the swap area of the disk.
- 3) Boot the UNIX system on the "mini root".
- 4) Restore the full root file system using *restore* (8).
- 5) Build a console floppy or cassette for bootstrapping.
- 6) Reboot the completed root file system.
- 7) Build and restore the /usr file system from tape with *tar* (1).

Certain of these steps are dependent on your hardware configuration. Formatting the disk pack used for the root file system may require using the DEC standard formatting programs. Also, if you are bootstrapping the system on an 11/750, no console cassette is created.

The following sections describe the above steps in detail. In these sections references to disk drives are of the form *xx(n,m)* and references to files on tape drives are of the form *yy(n,m)* where *xx* and *yy* are one of the names described in section 1.4 and *n* and *m* are the unit and offset numbers described in section 1.4. Commands you are expected to type are shown in roman, while that information printed by the system is shown emboldened. Throughout the installation steps the reboot switch on an 11/780 or 11/730 should be set to off; on an 11/750 set the power-on action to halt. (In normal operation an 11/780 or 11/730 will have the reboot switch on and an 11/750 will have the power-on action set to reboot/restart.)

If you encounter problems in following the instructions in this part of the document, refer to Appendix C for help in troubleshooting.

2.1. Step 1: formatting the disk

All disks used with 4.2BSD should be formatted to insure the proper handling of physically corrupted disk sectors. If you have DEC disk drives, you should use the standard DEC formatter to format your disks. If not, the *format* program included in the distribution, or a vendor supplied formatting program, may be used to format disks. The *format* program is capable of formatting any of the following supported distribution devices:

lw(1.5i) l.

EMULEX MASSBUS: AMPEX 300M, 330M, CDC 300M, FUJITSU 404M

EMULEX SC-21V UNIBUS: AMPEX 300M, 330M, CDC 300M, FUJITSU 160M, 404M

If you have run a pre-4.1BSD version of UNIX on the packs you are planning to use for bootstrapping it is likely that the bad sector information on the packs has been destroyed, since it was accessible as normal data in the last several tracks of the disk. You should therefore run the formatter again to make sure the information is valid.

On an 11/750, to use a disk pack as a bootstrap device, sectors 0 through 15, the disk sectors in the files “/vmunix” (the system image) and “/boot” (the program that loads the system image), and the file system indices that lead to these two files must not have any errors. On an 11/780 or 11/730, the “boot” program is loaded from the console medium and includes device drivers for the “hp” and “up” disks which perform ECC correction and bad sector forwarding; consequently, on these machines the system may be bootstrapped on these disks even if the disk is not error free in critical locations. In general, if the first 15884 sectors of your disk are clean you are safe; if not you can take your chances.

To load the *format* program, insert the distribution TU58 cassette or RX01 floppy disk in the appropriate console device (on the 11/730 use cassette 0) and perform the following steps.

If you have an 11/780 give the commands:

```
>>> HALT
>>> UNJAM
>>> LOAD FORMAT
>>> START 2
```

If you have an 11/750 give the commands:

```
>>> I
>>> B DDA0
= format
```

If you have an 11/730 give the commands:

```
>>> H
>>> I
>>> L DD0:FORMAT
>>> S 2
```

The *format* program should now be running and awaiting your input:

Disk format/check utility

Enable debugging (1=bse, 2=ecc, 3=bse+ecc)?

If you made a mistake loading the program off the TU58 cassette the “=” prompt should reappear and you can retype the program name. If something else happened, you may have a bad distribution cassette or floppy, or your hardware may be broken; refer to Appendix C for help in troubleshooting. If you are unable to load programs off the distributed medium, consult Appendix B for an alternate (more painful) approach.

Format will create sector headers and verify the integrity of each sector formatted by using the disk controller’s “write check” command. Remember *format* runs only on the **up** and **hp** drives indicated above. *Format* will prompt for the information required as shown below. If you make a mistake in answering questions, “#” erases the last character typed, and “@” erases the current input line.

```

Enable debugging (0=none, 1=bse, 2=ecc, 3=bse+ecc)?
Device to format? xx (0,0)
...(the old bad sector table is read; ignore any errors that occur here)...
Formatting drive xx0 on adaptor 0: verify (yes/no)? yes
Device data: #cylinders=842, #tracks=20, #sectors=48
Available test patterns are:
    1 - (f00f) RH750 worst case
    2 - (ec6d) media worst case
    3 - (a5a5) alternating 1's and 0's
    4 - (ffff) Severe burnin (takes several hours)
Pattern (one of the above, other to restart)? 2
Start formatting...make sure the drive is online
...(soft ecc's and other errors are reported as they occur)...
...(if 4 write check errors were found, the program terminates like this)...
Errors:
Write check: 4
Bad sector: 0
ECC: 0
Skip sector: 0
Total of 4 hard errors found.
Writing bad sector table at block 524256
(524256 is the block # of the first block in the bad sector table)
Done

```

Once the root device has been formatted, *format* will prompt for another disk to format. Halt the machine by typing "control-P" and "H" (the "H" is necessary only on an 11/780, but does not hurt on the other machines).

```

Enable debugging (1=bse, 2=ecc, 3=bse+ecc)?^P
>>> H

```

It may be necessary to format other drives before constructing file systems on them; this can be done at a later time with the steps just performed. *Format* can also be used in an extended test mode (pattern 4) that uses numerous test patterns in 46 passes to detect as many disk surface errors as possible; this test runs for many hours, depending on the CPU and controller. On an 11/780, this can be speeded up significantly by setting the clock fast.

2.2. Step 2: copying the mini-root file system

The second step is to run a simple program, *copy*, which copies a very small root file system into the second partition of the disk. This file system will serve as the base for creating the actual root file system to be restored. The version of the operating system maintained on the "mini-root" file system understands not to swap on top of itself, thereby allowing double use of the disk partition. *Copy* is loaded just as the *format* program was loaded; for example, on an 11/780:

```

lw(2i) l.
(copy mini root file system)
>>> LOAD COPY
>>> START 2
From: yy(y,1) (unit y, second tape file)
To: xx(x,1) (mini root is on drive x; second partition)
Copy completed: 205 records copied
From:

```

while for an 11/750:

```
lw(2i) l.
(copy mini root file system)
>>> B DDA0
= copy
From: yy(y,1)    (unit y, second tape file)
To: xx(x,1)    (mini root is on drive x; second partition)
Copy completed: 205 records copied
From:
```

and for an 11/730:

```
lw(2i) l.
(copy mini root file system)
>>> L DD0:COPY
>>> S 2
From: yy(y,1)    (unit y, second tape file)
To: xx(x,1)    (mini root is on drive x; second partition)
Copy completed: 205 records copied
From:

(As above, '#' erases characters and '@' erases lines.)
```

2.3. Step 3: booting from the mini-root file system

You now have the minimal set of tools necessary to create a root file system and restore the file system contents from tape. To access this file system load the bootstrap program and boot the version of unix which has been placed in the "mini-root":

```
lw(2i) l.
(load bootstrap program)
>>> LOAD BOOT
>>> START 2
Boot
: xx(x,1)vmunix  (bring in vmunix off mini root)
```

or, on an 11/750:

```
lw(2i) l.
(load bootstrap program)
>>> B DDA0
= boot
Boot
: xx(x,1)vmunix  (bring in vmunix off mini root)
```

or, on an 11/730:

```
lw(2i) l.
(load bootstrap program)
>>> L DD0:BOOT
>>> S 2
Boot
: xx(x,1)vmunix  (bring in vmunix off mini root)

(As above, '#' erases characters and '@' erases lines.)
```

The standalone boot program should then read the system from the mini root file system you just created, and the system should boot:

```
215564+64088+69764 start 0xf98
4.2 BSD UNIX #1: Sun Feb 6 15:02:15 PST 1983
real mem = xxx
avail mem = yyy
... information about available devices ...
root device?
```

The first three numbers are printed out by the bootstrap programs and are the sizes of different parts of the system (text, initialized and uninitialized data). The system also allocates several system data structures after it starts running. The sizes of these structures are based on the amount of available memory and the maximum count of active users expected, as declared in a system configuration description. This will be discussed later.

UNIX itself then runs for the first time and begins by printing out a banner identifying the release and version of the system that is in use and the date it was compiled.

Next the *mem* messages give the amount of real (physical) memory and the memory available to user programs in bytes. For example, if your machine has only 512K bytes of memory, then *xxx* will be 523264, 1024 bytes less than 512K. The system reserves the last 1024 bytes of memory for use in error logging and doesn't count it as part of real memory.

The messages that came out next show what devices were found on the current processor. These messages are described in *autoconf*(4). The distributed system may not have found all the communications devices you have (dh's and dz's), or all the mass storage peripherals you have if you have more than two of anything. This will be corrected soon, when you create a description of your machine to configure UNIX from. The messages printed at boot here contain much of the information that will be used in creating the configuration. In a correctly configured system most of the information present in the configuration description is printed out at boot time as the system verifies that each device is present.

The "root device?" prompt was printed by the system and is now asking you for the name of the root file system to use. This happens because the distribution system is a *generic* system. It can be bootstrapped on any VAX cpu and with its root device and paging area on any available disk drive. You should respond to the root device question with *xx0**. This response supplies two pieces of information: first, *xx0* indicates the disk it is running on is drive 0 of type *xx*, secondly the "*" indicates the system is running "atop" the paging area. The latter is most important, otherwise the system will attempt to page on top of itself and chaos will ensue. You will later build a system tailored to your configuration that will not ask this question when it is bootstrapped.

```
root device? xx0*
WARNING: preposterous time in file system -- CHECK AND RESET THE DATE!
erase ^?, kill ^U, intr ^C
#
```

The "erase ..." message is part of */.profile* that was executed by the root shell when it started. This message is present to remind you that the line character erase, line erase, and interrupt characters are set to be what is standard on DEC systems; this insures things are consistent with the DEC console interface characters.

2.4. Step 4: restoring the root file system

UNIX is now running, and the 'UNIX Programmer's manual' applies. The '#' is the prompt from the shell, and lets you know that you are the super-user, whose login name is "root". To complete installation of the bootstrap system two steps remain. First, the root file system must be created, and second a boot floppy or cassette must be constructed.

To create the root file system the shell script "xtr" should be run as follows:

```
# disk=xx0 type=tt tape=yy xtr
```

where *xx0* is the name of the disk on which the root file system is to be restored (unit 0), *tt* is the type of drive on which the root file system is to be restored (see the table below), and *yy* is the name of the tape drive on which the distribution tape is mounted.

If the root file system is to reside on a disk other than unit 0 (as shown in the information printed out during autoconfiguration), you will have to create the necessary special files in */dev* and use the appropriate value. For example, if the root should be placed on *hp1*, you must create */dev/rhp1a* and */dev/hp1a* using *mknod(8)*.

```
11|11.
```

```
Drive Type Drive Type
```

```

-
DEC RM03 type=rm03 DEC RM05 type=rm05
DEC RM80 type=rm80 DEC RP06 type=rp06
DEC RP07 type=rp07 DEC RK07 type=rk07
DEC RA80 type=ra80 DEC RA60 type=ra60
DEC RA81 type=ra81 DEC R80 type=rb80
CDC 9766 type=9766 CDC 9775 type=9775
AMPEX 300M type=9300 AMPEX 330M type=capricorn
FUJITSU 160M type=fuji160 FUJITSU 404M type=eagle
```

This will generate many messages regarding the construction of the file system and the restoration of the tape contents, but should eventually terminate with the messages:

```

...
Root filesystem extracted

If this is a 780, update floppy
If this is a 730, update the cassette
#
```

2.5. Step 5: creating a boot floppy or cassette

If the machine is an 11/780 or 11/730, a boot floppy or cassette should be constructed according to the instructions in chapter 4. For 11/750's, bootstrapping is performed by using a boot prom and special code located in sectors 0-15 of the root file system. The *newfs* program automatically installs the needed code, so you may continue on to the next step. On an 11/780 with interleaved memory, or other configurations that require alteration of the standard boot files, this step may be left for later.

2.6. Step 6: rebooting the completed root file system

With the above work completed, all that is left is to reboot:

```

# sync (synchronize file system state)
# ^P (halt machine)
>>> HALT (for 11/780's only)
>>> UNJAM (for 11/780's only)
>>> I (initialize processor state)
>>> B xxS (on an 11/750, use B/2)
...(boot program is eventually loaded)...
Boot
: xx(x,0)vmunix (vmunix brought in off root)
215564+64088+69764 start 0xf98
4.2 BSD UNIX #1: Sun Feb 6 15:02:15 PST 1983
real mem = xxx
avail mem = yyy
... information about available devices ...
root on xx0
WARNING: preposterous time in file system -- CHECK AND RESET THE DATE!
erase ^?, kill ^U, intr ^C
#

```

(see section 6.1 if the system does not reboot properly)

The system is now running single user on the installed root file system. The next section tells how to complete the installation of distributed software on the /usr file system.

2.7. Step 7: setting up the /usr file system

First set a shell variable to the name of your disk, so the commands we give will work regardless of the disk you have; do one of

```

11.
# disk=hp (if you have an RP06, RM03, RM05, RM80, or other MASSBUS drive)
# disk=hk (if you have RK07s)
# disk=ra (if you have UDA50 storage module drives)
# disk=up (if you have UNIBUS storage module drives)
# disk=rb (if you have IDC storage module drives)

```

The next thing to do is to extract the rest of the data from the tape. You might wish to review the disk configuration information in section 4.4 before continuing; the partitions used below are those most appropriate in size. Find the disk you have in the following table and execute the commands in the right hand portion of the table:

```
11.
DEC RM03 # name=hp0g; type=rm03
DEC RM05 # name=hp0g; type=rm05
DEC RM80 # name=hp0g; type=rm80
DEC RP06 # name=hp0g; type=rp06
DEC RP07 # name=hp0h; type=rp07
DEC RK07 # name=hk0g; type=rk07
DEC RA80 # name=ra0h; type=ra80
DEC RA60 # name=ra0h; type=ra60
DEC RA81 # name=ra0h; type=ra81
DEC R80  # name=rb0h; type=rb80
UNIBUS CDC 9766 # name=up0g; type=9766
UNIBUS AMPEX 300M # name=up0g; type=9300
UNIBUS AMPEX 330M # name=up0g; type=capricorn
UNIBUS FUJITSU 160M # name=up0g; type=fuji160
UNIBUS FUJITSU 404M # name=up0h; type=eagle
MASSBUS CDC 9766 # name=hp0g; type=9766
MASSBUS AMPEX 300M # name=hp0g; type=9300
MASSBUS AMPEX 330M # name=hp0g; type=capricorn
MASSBUS FUJITSU 404M # name=hp0h; type=eagle
```

Find the tape you have in the following table and execute the commands in the right hand portion of the table:

```
11.
DEC TE16/TU45/TU77 # cd /dev; MAKEDEV ht0; sync
DEC TU78 # cd /dev; MAKEDEV mt0; sync
DEC TS11 # cd /dev; MAKEDEV ts0; sync
EMULEX TC11 # cd /dev; MAKEDEV tm0; sync
SI 9700 # cd /dev; MAKEDEV ut0; sync
```

Then execute the following commands

```

lw(2i) l.
# date yymmddhhmm    (set date, see date (1))
....
# passwd root    (set password for super-user)
New password: (password will not echo)
Retype new password:
# newfs ${name} ${type}    (create empty user file system)
(this takes a few minutes)
# mount /dev/${name} /usr    (mount the usr file system)
# cd /usr    (make /usr the current directory)
# mkdir sys (make directory for system source)
# cd sys    (make /usr/sys the current directory)
# mt fsf
# tar xpbf 20 /dev/rmt12    (extract the system source)
(this takes about 5-10 minutes)
# cd ..(back to /usr)
# mt fsf
# tar xpbf 20 /dev/rmt12    (extract all of usr except usr/src)
(this takes about 15-20 minutes)
# cd / (back to root)
# chmod 755 / /usr /usr/sys
# rm -f sys
# ln -s /usr/sys sys    (make a symbolic link to the system source)
# umount /dev/${name} (unmount /usr)

```

The data on the fourth and fifth tape files has now been extracted and the first reel of the distribution is no longer needed. The remainder of the installation procedure uses the second reel of tape which should be mounted in place of the first.

You can check the consistency of the /usr file system by doing

```
# fsck /dev/r${name}
```

The output from *fsck* should look something like:

```

** /dev/rxx0h
** Last Mounted on /usr
** Phase 1 - Check Blocks and Sizes
** Phase 2 - Check Pathnames
** Phase 3 - Check Connectivity
** Phase 4 - Check Reference Counts
** Phase 5 - Check Cyl groups
671 files, 3497 used, 137067 free (75 frags, 34248 blocks)

```

If there are inconsistencies in the file system, you may be prompted to apply corrective action; see the document describing *fsck* for information.

To use the /usr file system, you should now remount it by saying

```
# /etc/mount /dev/${name} /usr
```

You can now extract the first file on the second tape (the source for the commands). If you have RK07's you must first put a formatted pack in drive 1 and set up a UNIX file system on it by doing:

```

# newfs hk1g rk07
(this takes a few minutes)
# mount /dev/hk1g /usr/src
# cd /usr/src

```

In any case you can then extract the source code for the commands (except on RK07's this will fit in the

/usr file system):

```
# mkdir /usr/src
# chmod 755 /usr/src
# cd /usr/src
# tar xpb 20
```

If you get an error at this point, you can reposition the tape with the following command and try the above commands again.

```
# mt rew
```

2.8. Additional software

There are three extra tape files on the distribution tapes which have not been installed to this point. They are a font library for use with Varian and Versatec printers, the Ingres database system, and user contributed software. All three tapes files are in *tar* (1) format and can be installed by positioning the tape and reading in the files as was done for /usr/src above. As distributed, the fonts should be placed in a directory /usr/lib/vfont, the Ingres system should be placed in /usr/ingres, and the user contributed software should be placed in /usr/src/new. The exact contents of the user contributed software is given in a separate document.

3. UPGRADING A 4BSD SYSTEM

Begin by reading the other parts of this document to see what has changed since the last time you bootstrapped the system. Also read the "Changes in 4.2BSD" document, and look at the new manual sections provided to you. If you have local system modifications to the kernel to install, look at the document "Kernel changes in 4.2BSD" to get an idea of how the system changes will affect your local mods.

If you are running a version of the system distributed prior to 4.0BSD, you are pretty much on your own. Sites running 3BSD or 32/V may be able to modify the restor program to understand the old 512 byte block file system, but this has never been tried. This section assumes you are running 4.1BSD.

3.1. Step 1: what to save

No matter what version of the system you may be running, you will have to rebuild your root and usr file systems. The easiest way to do this is to save the important files on your existing system, perform a bootstrap as if you were installing 4.2BSD on a brand new machine, then merge the saved files into the new system. The following list enumerates the standard set of files you will want to save and indicates directories in which site specific files should be present. This list will likely be augmented with non-standard files you have added to your system; be sure to do a tar of the directories /etc, /lib, and /usr/lib to guard against your missing something the first time around.

```

11.
/.profile    root sh startup script
/.login      root csh startup script
/.cshrc      root csh startup script
/dev/MAKEfor the LOCAL case for making devices
/etc/fstab   disk configuration data
/etc/group   group data base
/etc/passwd  user data base
/etc/rcfor any local additions
/etc/ttys    terminal line configuration data
/etc/ttytype terminal line to terminal type mapping data
/etc/termcapfor any local entries which may have been added
/lib         for any locally developed language processors
/usr/dict/*  for local additions to words and papers
/usr/include/* for local additions
/usr/lib/aliases mail forwarding data base
/usr/lib/crontab cron daemon data base
/usr/lib/font/* for locally developed font libraries
/usr/lib/lint/* for locally developed lint libraries
/usr/lib/tabset/* for locally developed tab setting files
/usr/lib/term/* for locally developed nroff drive tables
/usr/lib/tmac/* for locally developed troff/nroff macros
/usr/lib/uucp/* for local uucp configuration files
/usr/man/man1 for manual pages for locally developed programs
/usr/msgs    for current msgs
/usr/spool/* for current mail, news, uucp files, etc.
/usr/src/local for source for locally developed programs

```

As 4.1BSD binary images will run unchanged under 4.2BSD you should be certain to save any programs such as compilers which you will need in bootstrapping to 4.2BSD.*

* 4.2BSD can support a "4.1BSD compatibility mode" of system operation whereby system calls from 4.1BSD are either emulated or safely ignored. There are only two exceptions; programs which read directories or use the old jobs library will not operate properly. However, while 4.1BSD binaries will execute under 4.2BSD it is **STRONGLY RECOMMENDED** that the programs be recompiled under the new system. Refer to the docu-

Once you have saved the appropriate files in a convenient format, the next step is to dump your file systems with *dump*(8). For the utmost of safety this should be done to magtape. However, if you enjoy gambling with your life (or you have a VERY friendly user community) and you have sufficient disk space, you can try converting your file systems in-place by using a disk partition. If you select the latter tact, a version of the 4.1BSD dump program which runs under 4.2 is provided in `/etc/dump.4.1`; be sure to read through this entire document before beginning the conversion. Beware that file systems created under 4.2BSD will use about 5-10% more disk space for file system related information than under 4.1BSD. Thus, before dumping each file system it is a good idea to remove any files which may be easily regenerated. Since most all programs will likely be recompiled under the new system your best bet is to remove any object files. File systems with at least 10% free space on them should restore into an equivalently sized 4.2BSD file system without problem.

Once you have dumped the file systems you wish to convert to 4.2BSD, install the system from the bootstrap tape as described in chapter 2, then proceed to the next section.

3.2. Step 2: merging

When your system is booting reliably and you have the 4.2BSD root and /usr file systems fully installed you will be ready to proceed to the next step in the conversion process: merging your old files into the new system.

Using the tar tape, or tapes, you created in step 1 extract the appropriate files into a scratch directory, say `/usr/convert`:

```
# mkdir /usr/convert
# cd /usr/convert
# tar x
```

Certain data files, such as those from the `/etc` directory, may simply be copied into place.

```
# cp passwd group fstab ttys ttytype /etc
# cp crontab /usr/lib
```

Other files, however, must be merged into the distributed versions by hand. In particular, be careful with `/etc/termcap`.

The commands kept under the LOCAL entry in `/dev/MAKE` should be placed in the new shell script `/dev/MAKEDEV.local` so that saying "MAKEDEV LOCAL" will create the appropriate local devices and device names. If you have any homegrown device drivers which use major device numbers reserved by the system you will have to modify the commands used to create the devices or alter the system device configuration tables in `/sys/vax/conf.c`.

The spooling directories saved on tape may be restored in their eventual resting places without too much concern. Be sure to use the 'p' option to tar so that files are recreated with the same file modes:

```
# cd /usr
# tar xp msgs spool/mail spool/uucp spool/uucppublic spool/news
```

Whatever else is left is likely to be site specific or require careful scrutiny before placing in its eventual resting place. Refer to the documentation and source code before arbitrarily overwriting a file.

3.3. Step 3: converting file systems

The dump format used in 4.0 and 4.1BSD is upward compatible with that used in 4.2BSD. That is, the 4.2BSD *restore* program understands how to read old dump tapes, although 4.2BSD dump tapes may not be properly restored under 4.0BSD or 4.1BSD. To convert a file system dumped to magtape, simply create the appropriate file system and restore the data. Note that the 4.2BSD *restore* program does its work on a mounted file system using normal system operations (unlike the older *restor* which accessed the raw file system device and deposited inodes in the appropriate locations on disk). This means that file system dumps may be restored even if the characteristics of the file system changed. To restore a dump tape for,

ment "Changes in 4.2BSD" for elaboration on this point.

say, the /a file system something like the following would be used:

```
# mkdir /a
# newfs hp1g eagle
# mount /dev/hp1g /a
# cd /a
# restore r
```

If tar images were written instead of doing a dump, you should be sure to use the 'p' option when reading the files back. No matter how you restore a file system, be sure and check its integrity with fsck when the job is complete.

3.4. Bootstrapping language processors

To convert a compiler from 4.1BSD to 4.2BSD you should simply have to recompile and relink the various parts. If the processor is written in itself, for instance a PASCAL compiler written in PASCAL, the important step in converting is to save a working copy of the 4.1BSD binary before converting to 4.2BSD. Then, once the system has been changed over, the 4.1BSD binary should be used in the rebuilding process. In order to do this, you should enable the 4.1 compatibility option when you configure the kernel (below).

If no working 4.1BSD binary exists, or the language processor uses some nonstandard system call, you will likely have to compile the language processor into an intermediate form, such as assembly language, on a 4.1BSD system, then bring the intermediate form to 4.2BSD for assembly and loading.

4. SYSTEM SETUP

This section describes procedures used to setup a VAX UNIX system. Procedures described here are used when a system is first installed or when the system configuration changes. Procedures for normal system operation are described in the next section.

4.1. Making a UNIX boot floppy

If you have an 11/780 you will want to create a UNIX boot floppy by adding some files to a copy of your current DEC console floppy, using *fcopy*(8) and *arff*(8). This floppy will make standalone system operations such as bootstrapping much easier.

First change into the directory where the console floppy information is stored:

```
# cd /sys/floppy
```

then set up the default boot device. If you have an RK07 as your primary root do:

```
# cp defboo.hk defboo.cmd
```

If you have a drive on a UDA50 (e.g. an RA81) as your primary root do:

```
# cp defboo.ra defboo.cmd
```

If you have a second vendor UNIBUS storage module as your primary root do:

```
# cp defboo.up defboo.cmd
```

Otherwise:

```
# cp defboo.hp defboo.cmd
```

If the local configuration requires any changes in *restar.cmd* or *defboo.cmd* (e.g., for interleaved memory controllers), these should be made now. The following command will then copy your DEC local console floppy, updating the copy appropriately.

```
# make update
```

Change Floppy, Hit return when done.

(waits for you to put clean floppy in console)

Are you sure you want to clobber the floppy? yes

More copies of this floppy can be made using *fcopy*(8).

4.2. Making a UNIX boot cassette

If you have an 11/730 you will want to create a UNIX boot cassette by adding some files to a copy of your current DEC console cassette, using *fcopy*(8) and *arff*(8). This cassette will make standalone system operations such as bootstrapping much easier.

First change into the directory where the console cassette information is stored:

```
# cd /sys/cassette
```

then set up the default boot device. If you have an IDC storage module as your primary root do:

```
# cp defboo.rb defboo.cmd
```

If you have an RK07 as your primary root do:

```
# cp defboo.hk defboo.cmd
```

If you have a drive on a UDA50 as your primary root do:

```
# cp defboo.ra defboo.cmd
```

Otherwise:

```
# cp defboo.up defboo.cmd
```

To complete the procedure place your DEC local console cassette in drive 0 (the drive at front of the CPU); the following command will then copy it, updating the copy appropriately.

```
# make update
```

Change Floppy, Hit return when done.

(waits for you to put clean cassette in console drive 0)

Are you sure you want to clobber the floppy? yes

More copies of this cassette can best be made using *dd(1)*.

4.3. Kernel configuration

This section briefly describes the layout of the kernel code and how files for devices are made. For a full discussion of configuring and building system images, consult the document "Building 4.2BSD UNIX Systems with Config".

4.3.1. Kernel organization

As distributed, the kernel source is in a separate tar image. The source may be physically located anywhere within any file system so long as a symbolic link to the location is created for the file */sys* (many files in */usr/include* are normally symbolic links relative to */sys*). In further discussions of the system source all path names will be given relative to */sys*.

The directory */sys/sys* contains the mainline machine independent operating system code. Files within this directory are conventionally named with the following prefixes.

```
lw(1.0i) l.
init_ system initialization
kern_ kernel (authentication, process management, etc.)
quota_ disk quotas
sys_ system calls and similar
tty_ terminal handling
ufs_ file system
uipc_ interprocess communication
vm_ virtual memory
```

The remaining directories are organized as follows.

```
lw(1.0i) l.
/sys/h machine independent include files
/sys/conf site configuration files and basic templates
/sys/net network independent, but network related code
/sys/netinet DARPA Internet code
/sys/netimp IMP support code
/sys/netpup PUP-1 support code
/sys/vax VAX specific mainline code
/sys/vaxif VAX network interface code
/sys/vaxmba VAX MASSBUS device drivers and related code
/sys/vaxuba VAX UNIBUS device drivers and related code
```

Many of these directories are referenced through */usr/include* with symbolic links. For example, */usr/include/sys* is a symbolic link to */sys/h*. The system code, as distributed, is totally independent of the include files in */usr/include*. This allows the system to be recompiled from scratch without the */usr* file system mounted.

4.3.2. Devices and device drivers

Devices supported by UNIX are implemented in the kernel by drivers whose source is kept in `/sys/vax`, `/sys/vaxuba`, or `/sys/vaxmba`. These drivers are loaded into the system when included in a cpu specific configuration file kept in the `conf` directory. Devices are accessed through special files in the file system, made by the `mknod(8)` program and normally kept in the `/dev` directory. For all the devices supported by the distribution system, the files in `/dev` are created by the `/dev/MAKEDEV` shell script.

Determine the set of devices that you have and create a new `/dev` directory by running the `MAKEDEV` script. First create a new directory `/newdev`, copy `MAKEDEV` into it, edit the file `MAKEDEV.local` to provide an entry for local needs, and run it to generate a `/newdev` directory. For instance, if your machine has a single `dz-11`, a single `dh-11`, a single `dmf-32`, an `rm03` disk, an `EMULEX` controller, an `AMPEX-9300` disk, and a `te16` tape drive you would do:

```
# cd /
# mkdir newdev
# cp dev/MAKEDEV newdev/MAKEDEV
# cd newdev
# MAKEDEV dz0 dh0 dmf0 hp0 up0 ht0 std LOCAL
```

Note the “`std`” argument causes standard devices such as `/dev/console`, the machine console, `/dev/floppy`, the console floppy disk interface for the `11/780`, and `/dev/tu0` and `/dev/tu1`, the console cassette interfaces for the `11/750` and `11/730`, to be created.

You can then do

```
# cd /
# mv dev olddev ; mv newdev dev
# sync
```

to install the new device directory.

4.3.3. Building new system images

The kernel configuration of each UNIX system is described by a single configuration file, stored in the `/sys/conf` directory. To learn about the format of this file and the procedure used to build system images, start by reading “Building 4.2BSD UNIX Systems with Config”, look at the manual pages in section 4 of the UNIX manual for the devices you have, and look at the configuration files in the `/sys/conf` directory.

The configured system image “`vmunix`” should be copied to the root, and then booted to try it out. It is best to name it `/newvmunix` so as not to destroy the working system until you’re sure it does work:

```
# cp vmunix /newvmunix
# sync
```

It is also a good idea to keep the old system around under some other name. In particular, we recommend that you save the generic distribution version of the system permanently as `/genvmunix` for use in emergencies.

To boot the new version of the system you should follow the bootstrap procedures outlined in section 6.1. A systematic scheme for numbering and saving old versions of the system is best.

4.4. Disk configuration

This section describes how to layout file systems to make use of the available space and to balance disk load for better system performance.

4.4.1. Initializing `/etc/fstab`

Change into the directory `/etc` and copy the appropriate file from:

```
fstab.rm03
fstab.rm05
fstab.rm80
fstab.ra60
fstab.ra80
fstab.ra81
fstab.rb80
fstab.rp06
fstab.rp07
fstab.rk07
fstab.up160m (160Mb up drives)
fstab.up300m (300Mb up drives)
fstab.hp400m (400Mb hp drives)
fstab.up (other up drives)
fstab.hp (other hp drives)
```

to the file `/etc/fstab`, i.e.:

```
# cd /etc
# cp fstab.xxx fstab
```

This will set up the initial information about the usage of disk partitions, which we see how to update more below.

4.4.2. Disk naming and divisions

Each physical disk drive can be divided into up to 8 partitions; UNIX typically uses only 3 or 4 partitions. For instance, on an RM03 or RP06, the first partition, hp0a, is used for a root file system, a backup thereof, or a small file system like, `/tmp`; the second partition, hp0b, is used for paging and swapping; and the third partition hp0g holds a user file system. On an RM05, the first three partitions are used as for the RM03, and the fourth partition, hp0h, is used to hold the `/usr` file system, including source code.

The disk partition sizes for a drive are based on a set of four default partition tables; c.f. *diskpart* (8). The particular table used is dependent on the size of the drive. The “a” partition is the same size across all drives, 15884 sectors. The “b” partition, used for paging and swapping, is sized according to the total space on the disk. For drives less than about 400 megabytes the partition is 33440 sectors, while for larger drives the partition size is doubled to 66880 sectors. The “c” partition is always used to access the entire physical disk, including the space at the back of the disk reserved for the bad sector forwarding table. If the disk is larger than about 250 megabytes, an “h” partition is created with size 291346 sectors, and no matter whether the “h” partition is created or not, the remainder of the drive is allocated to the “g” partition. Sites which want to split up the “g” partition into a number of smaller file systems may use the “d”, “e”, and “f” partitions which overlap the “g” partition. The default sizes for these partitions are 15884, 55936, and the remainder of the disk, respectively*.

4.4.3. Space available

The space available on a disk varies per device. The amount of space available on the common disk partitions is listed in the following table. Not shown in the table are the partitions of each drive devoted to the root file system and the paging area.

* These rules are, unfortunately not evenly applied to all disks. Drives on DEC UDA50 and IDC controllers do not completely follow these rules; in particular, the swap partition on an RA81 is only 33440 sectors, and no “d”, “e”, or “f” partitions are available on an RA60 or RA80. Consult *uda* (4) for more information.

```

center;
l l n l n.
Type Name Size Name Size
-
rk07 hk?g 13 Mb
rm03 hp?g 41 Mb
rp06 hp?g 145 Mb
rm05 hp?g 80 Mb hp?h 145 Mb
rm80 hp?g 96 Mb
ra60 ra?g 41 Mb ra?h 139 Mb
ra80 ra?g 41 Mb ra?h 56 Mb
ra81 ra?g 41 Mb ra?h 380 Mb
rb80 rb?g 41 Mb rb?h 56 Mb
rp07 hp?g 315 Mb hp?h 145 Mb
up300 up?g 80 Mb up?h 145 Mb
hp400 hp?g 216 Mb hp?h 145 Mb
up160 up?g 106 Mb

```

Here up300 refers to either an AMPEX or CDC 300 Megabyte disk on a UNIBUS disk controller, up160 refers to a FUJITSU 160 Megabyte disk on the UNIBUS, and hp400 refers to a FUJITSU Eagle 400 Megabyte disk on a MASBUS disk controller. Consult the manual pages for the specific controllers for other supported disks or other partitions.

Each disk also has a paging area, typically of 16 Megabytes, and a root file system of 8 Megabytes. The distributed system binaries occupy about 22 Megabytes while the major sources occupy another 25 Megabytes. This overflows dual RK07 and dual RL02 systems, but fits easily on most other hardware configurations.

Be aware that the disks have their sizes measured in disk sectors (512 bytes), while the UNIX file system blocks are variable sized. All user programs report disk space in kilobytes and, where needed, disk sizes are always specified in terms of sectors. The `/etc/disktab` file used in making file systems specifies disk partition sizes in sectors; the default sector size of 512 bytes may be overridden with the "se" attribute.

4.4.4. Layout considerations

There are several considerations in deciding how to adjust the arrangement of things on your disks: the most important is making sure there is adequate space for what is required; secondarily, throughput should be maximized. Paging space is an important parameter. The system, as distributed, sizes the configured paging areas each time the system is booted. Further, multiple paging areas of different size may be interleaved. Drives smaller than 400 megabytes have swap partitions of 16 megabytes while drives larger than 400 megabytes have 32 megabytes. These values may be changed to get more paging space by changing the appropriate partition table in the disk driver.

Many common system programs (C, the editor, the assembler etc.) create intermediate files in the `/tmp` directory, so the file system where this is stored also should be made large enough to accommodate most high-water marks; if you have several disks, it makes sense to mount this in a "root" (i.e. first partition) file system on another disk. All the programs that create files in `/tmp` take care to delete them, but are not immune to rare events and can leave dregs. The directory should be examined every so often and the old files deleted.

The efficiency with which UNIX is able to use the CPU is often strongly affected by the configuration of disk controllers. For general time-sharing applications, the best strategy is to try to split the root file system (`/`), system binaries (`/usr`), the temporary files (`/tmp`), and the user files among several disk arms, and to interleave the paging activity among a several arms.

It is critical for good performance to balance disk load. There are at least five components of the disk load that you can divide between the available disks:

1. The root file system.
2. The /tmp file system.
3. The /usr file system.
4. The user files.
5. The paging activity.

The following possibilities are ones we have used at times when we had 2, 3 and 4 disks:

center	doublebox;	1		c	s	s	1		lw(5)		lw(5)		lw(5).	disks	what	2	3	4	_	/	1	2	2	
tmp	1	3	4	usr	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
archive	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

The most important things to consider are to even out the disk load as much as possible, and to do this by decoupling file systems (on separate arms) between which heavy copying occurs. Note that a long term average balanced load is not important... it is much more important to have instantaneously balanced load when the system is busy.

Intelligent experimentation with a few file system arrangements can pay off in much improved performance. It is particularly easy to move the root, the /tmp file system and the paging areas. Place the user files and the /usr directory as space needs dictate and experiment with the other, more easily moved file systems.

4.4.5. File system parameters

Each file system is parameterized according to its block size, fragment size, and the disk geometry characteristics of the medium on which it resides. Inaccurate specification of the disk characteristics or haphazard choice of the file system parameters can result in substantial throughput degradation or significant waste of disk space. As distributed, file systems are configured according to the following table.

center;		
111.		
File system	Block size	Fragment size
—		
/	8 Kbytes	1 Kbytes
usr	4 Kbytes	512 bytes
users	4 Kbytes	1 Kbytes

The root file system block size is made large to optimize bandwidth to the associated disk; this is particularly important since the /tmp directory is normally part of the root file. The large block size is also important as many of the most heavily used programs are demand paged out of the /bin directory. The fragment size of 1 Kbytes is a “nominal” value to use with a file system. With a 1 Kbyte fragment size disk space utilization is approximately the same as with the earlier versions of the file system.

The usr file system uses a 4 Kbyte block size with 512 byte fragment size in an effort to get high performance while conserving the amount of space wasted by a large fragment size. Space compaction has been deemed important here because the source code for the system is normally placed on this file system.

The file systems for users have a 4 Kbyte block size with 1 Kbyte fragment size. These parameters have been selected based on observations of the performance of our user file systems. The 4 Kbyte block size provides adequate bandwidth while the 1 Kbyte fragment size provides acceptable space compaction and disk fragmentation.

Other parameters may be chosen in constructing file systems, but the factors involved in choosing a block size and fragment size are many and interact in complex ways. Larger block sizes result in better throughput to large files in the file system as larger i/o requests will then be performed by the system. However, consideration must be given to the average file sizes found in the file system and the performance of the internal system buffer cache. The system currently provides space in the inode for 12 direct block pointers, 1 single indirect block pointer, and 1 double indirect block pointer.* If a file uses only direct

blocks, access time to it will be optimized by maximizing the block size. If a file spills over into an indirect block, increasing the block size of the file system may decrease the amount of space used by eliminating the need to allocate an indirect block. However, if the block size is increased and an indirect block is still required, then more disk space will be used by the file because indirect blocks are allocated according to the block size of the file system.

In selecting a fragment size for a file system, at least two considerations should be given. The major performance tradeoffs observed are between an 8 Kbyte block file system and a 4 Kbyte block file system. Due to implementation constraints, the block size / fragment size ratio can not be greater than 8. This means that an 8 Kbyte file system will always have a fragment size of at least 1 Kbytes. If a file system is created with a 4 Kbyte block size and a 1 Kbyte fragment size, then upgraded to an 8 Kbyte block size and 1 Kbyte fragment size, identical space compaction will be observed. However, if a file system has a 4 Kbyte block size and 512 byte fragment size, converting it to an 8K/1K file system will result in significantly more space being used. This implies that 4 Kbyte block file systems which might be upgraded to 8 Kbyte blocks for higher performance should use fragment sizes of at least 1 Kbytes to minimize the amount of work required in conversion.

A second, more important, consideration when selecting the fragment size for a file system is the level of fragmentation on the disk. With a 512 byte fragment size, storage fragmentation occurs much sooner, particularly with a busy file system running near full capacity. By comparison, the level of fragmentation in a 1 Kbyte fragment file system is an order of magnitude less severe. This means that on file systems where many files are created and deleted the 512 byte fragment size is more likely to result in apparent space exhaustion due to fragmentation. That is, when the file system is nearly full, file expansion which requires locating a contiguous area of disk space is more likely to fail on a 512 byte file system than on a 1 Kbyte file system. To minimize fragmentation problems of this sort, a parameter in the super block specifies a minimum acceptable free space threshold. When normal users (i.e. anyone but the super-user) attempt to allocate disk space and the free space threshold is exceeded, the user is returned an error as if the file system were actually full. This parameter is nominally set to 10%; it may be changed by supplying a parameter to *newfs*, or by patching the super block of an existing file system.

In general, unless a file system is to be used for a special purpose application (for example, storing image processing data), we recommend using the default values supplied. Remember that the current implementation limits the block size to at most 8 Kbytes and the ratio of block size / fragment size must be in the range 1-8.

The disk geometry information used by the file system affects the block layout policies employed. The file */etc/disktab*, as supplied, contains the data for most all drives supported by the system. When constructing a file system you should use the *newfs* (8) program and specify the type of disk on which the file system resides. This file also contains the default file system partition sizes, and default block and fragment sizes. To override any of the default values you can modify the file or use one of the options to *newfs*.

4.4.6. Implementing a layout

To put a chosen disk layout into effect, you should use the *newfs* (8) command to create each new file system. Each file system must also be added to the file */etc/fstab* so that it will be checked and mounted when the system is bootstrapped.

As an example, consider a system with *rm03*'s. On the first *rm03*, *hp0*, we will put the root file system in *hp0a*, and the */usr* file system in *hp0g*, which has enough space to hold it and then some. The */tmp* directory will be part of the root file system, as no file system will be mounted on */tmp*. If we had only one *rm03*, we would put user files in the *hp0g* partition with the system source and binaries.

If we had a second *rm03*, we would create a file system in *hp1g* and put user files there, calling the file system */mnt*. We would also interleave the paging between the 2 *rm03*'s. To do this we would build a system configuration that specified:

```
config      vmunix      root on hp0 swap on hp0 and hp1
```

to get the swap interleaved, and add the lines

* A triple indirect block pointer is also reserved, but not currently supported.

```
/dev/hp1b::sw::
/dev/hp1g:/mnt:rw:1:2
```

to the `/etc/fstab` file. We would keep a backup copy of the root file system in the **hp1a** disk partition.

To make the `/mnt` file system we would do:

```
# cd /dev
# MAKEDEV hp1
# newfs hp1g rm03
(information about file system prints out)
# mkdir /mnt
# mount /dev/hp1g /mnt
```

4.5. Configuring terminals

If UNIX is to support simultaneous access from more than just the console terminal, the file `/etc/ttys` (*ttys*(5)) has to be edited.

Terminals connected via dz interfaces are conventionally named **ttyDD** where DD is a decimal number, the “minor device” number. The lines on dz0 are named `/dev/tty00`, `/dev/tty01`, ... `/dev/tty07`. Lines on dh or dmf interfaces are conventionally named **tyhX**, where X is a hexadecimal digit. If more than one dh or dmf interface is present in a configuration, successive terminals would be named **tyiX**, **tyjX**, etc.

To add a new terminal, be sure the device is configured into the system and that the special file for the device has been made by `/dev/MAKEDEV`. Then, set the first character of the appropriate line of `/etc/ttys` to 1 (or add a new line).

The second character of each line in the `/etc/ttys` file lists the speed and initial parameter settings for the terminal. The commonly used choices are:

```
0    300-1200-150-110
2    9600
3    1200-300
5    300-1200
```

Here the first speed is the speed a terminal starts at, and “break” switches speeds. Thus a newly added terminal `/dev/tty00` could be added as

```
12tty00
```

if it was wired to run at 9600 baud. The definition of each “terminal type” is located in the file `/etc/gettytab` and read by the *getty* program. To make custom terminal types, consult *gettytab*(5) before modifying this file.

Dialup terminals should be wired so that carrier is asserted only when the phone line is dialed up. For non-dialup terminals from which modem control is not available, you must either wire back the signals so that the carrier appears to always be present, or show in the system configuration that carrier is to be assumed to be present. See *dh*(4), *dz*(4), and *dmf*(4) for details.

You should also edit the file `/etc/ttytype` placing the type of each new terminal there (see *ttytype*(5)).

When the system is running multi-user, all terminals that are listed in `/etc/ttys` having a 1 as the first character of their line are enabled. If, during normal operations, it is desired to disable a terminal line, you can edit the file `/etc/ttys` and change the first character of the corresponding line to be a 0 and then send a hangup signal to the *init* process, by doing

```
# kill -1 1
```

Terminals can similarly be enabled by changing the first character of a line from a 0 to a 1 and sending a hangup signal to *init*.

Note that several programs, `/usr/src/etc/init.c` and `/usr/src/etc/comsat.c` in particular, will have to be recompiled if there are to be more than 100 terminals. Also note that if a special file is inaccessible when

init tries to create a process for it, *init* will print a message on the console and try to reopen the terminal every minute, reprinting the warning message every 10 minutes.

Finally note that you should change the names of any dialup terminals to *ttyd?* where ? is in [0-9a-f], as some programs use this property of the names to determine if a terminal is a dialup. Shell commands to do this should be put in the */dev/MAKEDEV.local* script.

While it is possible to use truly arbitrary strings for terminal names, the accounting and noticeably the *ps*(1) command make good use of the convention that *tty* names (by default, and also after dialups are named as suggested above) are distinct in the last 2 characters. Change this and you may be sorry later, as the heuristic *ps*(1) uses based on these conventions will then break down and *ps* will run MUCH slower.

4.6. Adding users

New users can be added to the system by adding a line to the password file */etc/passwd*. The procedure for adding a new user is described in *adduser*(8).

You should add accounts for the initial user community, giving each a directory and a password, and putting users who wish to share software in the same groups.

A number of guest accounts have been provided on the distribution system; these accounts are for people at Berkeley, DEC and at Bell Laboratories who have done major work on UNIX in the past. You can delete these accounts, or leave them on the system if you expect that these people would have occasion to login as guests on your system.

4.7. Site tailoring

All programs which require the site's name, or some similar characteristic, obtain the information through system calls or from files located in */etc*. Aside from parts of the system related to the network, to tailor the system to your site you must simply select a site name, then edit the file

/etc/rc.local

The first line in */etc/rc.local*,

/bin/hostname mysitename

defines the value returned by the *gethostname*(2) system call. Programs such as *getty*(8), *mail*(1), *wall*(1), *uucp*(1), and *who*(1) use this system call so that the binary images are site independent.

4.8. Setting up the line printer system

The line printer system consists of at least the following files and commands:

- 11.
- /usr/ucb/lpq* spooling queue examination program
- /usr/ucb/lprm* program to delete jobs from a queue
- /usr/ucb/lpr* program to enter a job in a printer queue
- /etc/printcap* printer configuration and capability data base
- /usr/lib/lpd* line printer daemon, scans spooling queues
- /etc/lpc* line printer control program

The file */etc/printcap* is a master data base describing line printers directly attached to a machine and, also, printers accessible across a network. The manual page *printcap*(5) describes the format of this data base and also indicates the default values for such things as the directory in which spooling is performed. The line printer system handles multiple printers, multiple spooling queues, local and remote printers, and also printers attached via serial lines which require line initialization such as the baud rate. Raster output devices such as a Varian or Versatec, and laser printers such as an Imagen, are also supported by the line printer system.

Remote spooling via the network is handled with two spooling queues, one on the local machine and one on the remote machine. When a remote printer job is initiated with *lpr*, the job is queued locally and a

daemon process created to oversee the transfer of the job to the remote machine. If the destination machine is unreachable, the job will remain queued until it is possible to transfer the files to the spooling queue on the remote machine. The *lpq* program shows the contents of spool queues on both the local and remote machines.

To configure your line printers, consult the *printcap* manual page and the accompanying document, "4.2BSD Line Printer Spooler Manual". A call to the *lpd* program should be present in */etc/rc*.

4.9. Setting up the mail system

The mail system consists of the following commands:

```

11.
/bin/mail    old standard mail program (from 32/V)
/usr/ucb/mail  UCB mail program, described in mail(1)
/usr/lib/sendmail  mail routing program
/usr/spool/mail  mail spooling directory
/usr/spool/secretmail  secure mail directory
/usr/bin/xsend  secure mail sender
/usr/bin/xget  secure mail receiver
/usr/lib/aliases  mail forwarding information
/usr/ucb/newaliases  command to rebuild binary forwarding database
/usr/ucb/biffmail  notification enabler
/etc/comsat  mail notification daemon
/etc/syslog  error message logger, used by sendmail

```

Mail is normally sent and received using the *mail*(1) command, which provides a front-end to edit the messages sent and received, and passes the messages to *sendmail*(8) for routing. The routing algorithm uses knowledge of the network name syntax, aliasing and forwarding information, and network topology, as defined in the configuration file */usr/lib/sendmail.cf*, to process each piece of mail. Local mail is delivered by giving it to the program */usr/bin/mail* which adds it to the mailboxes in the directory */usr/spool/mail/username*, using a locking protocol to avoid problems with simultaneous updates. After the mail is delivered, the local mail delivery daemon */etc/comsat* is notified, which in turn notifies users who have issued a "biff y" command that mail has arrived.

Mail queued in the directory */usr/spool/mail* is normally readable only by the recipient. To send mail which is secure against any possible perusal (except by a code-breaker) you should use the secret mail facility, which encrypts the mail so that no one can read it.

To setup the mail facility you should read the instructions in the file *READ_ME* in the directory */usr/src/usr.lib/sendmail* and then adjust the necessary configuration files. You should also set up the file */usr/lib/aliases* for your installation, creating mail groups as appropriate. Documents describing *sendmail*'s operation and installation are also included in the distribution.

4.9.1. Setting up a uucp connection

The version of *uucp* included in 4.2BSD is an enhanced version of that originally distributed with 32/V*. The enhancements include:

- support for many auto call units other than the DEC DN11,
- breakup of the spooling area into multiple subdirectories,
- addition of an *L.cmds* file to control the set of commands which may be executed by a remote site,
- enhanced "expect-send" sequence capabilities when logging in to a remote site,
- new commands to be used in polling sites and obtaining snap shots of *uucp* activity.

* The *uucp* included in this distribution is the result of work by many people; we gratefully acknowledge their contributions, but refrain from mentioning names in the interest of keeping this document current.

This section gives a brief overview of *uucp* and points out the most important steps in its installation.

To connect two UNIX machines with a *uucp* network link using modems, one site must have an auto-call unit and the other must have a dialup port. It is better if both sites have both.

You should first read the paper in volume 2B of the Unix Programmers Manual: "Uucp Implementation Description". It describes in detail the file formats and conventions, and will give you a little context. In addition, the document setup.tblms, located in the directory /usr/src/usr.bin/uucp/UUAIDS, may be of use in tailoring the software to your needs.

The *uucp* support is located in three major directories: /usr/bin, /usr/lib/uucp, and /usr/spool/uucp. User commands are kept in /usr/bin, operational commands in /usr/lib/uucp, and /usr/spool/uucp is used as a spooling area. The commands in /usr/bin are:

- 11.
- /usr/bin/uucp file-copy command
- /usr/bin/uux remote execution command
- /usr/bin/uusend binary file transfer using mail
- /usr/bin/uuencode binary file encoder (for *uusend*)
- /usr/bin/uudecode binary file decoder (for *uusend*)
- /usr/bin/uulog scans session log files
- /usr/bin/uusnap gives a snap-shot of *uucp* activity
- /usr/bin/uupoll polls remote system until an answer is received

The important files and commands in /usr/lib/uucp are:

- 11.
- /usr/lib/uucp/L-devices list of dialers and hardwired lines
- /usr/lib/uucp/L-dialcodes dialcode abbreviations
- /usr/lib/uucp/L.cmds commands remote sites may execute
- /usr/lib/uucp/L.syssystems to communicate with, how to connect, and when
- /usr/lib/uucp/SEQF sequence numbering control file
- /usr/lib/uucp/USERFILE remote site pathname access specifications
- /usr/lib/uucp/uuclean cleans up garbage files in spool area
- /usr/lib/uucp/uucico *uucp* protocol daemon
- /usr/lib/uucp/uuxqt *uucp* remote execution server

while the spooling area contains the following important files and directories:

- 11.
- /usr/spool/uucp/C. directory for command, "C." files
- /usr/spool/uucp/D. directory for data, "D.", files
- /usr/spool/uucp/X. directory for command execution, "X.", files
- /usr/spool/uucp/D.machine directory for local "D." files
- /usr/spool/uucp/D.machineX directory for local "X." files
- /usr/spool/uucp/TM. directory for temporary, "TM.", files
- /usr/spool/uucp/LOGFILE log file of *uucp* activity
- /usr/spool/uucp/SYSLOG log file of *uucp* file transfers

To install *uucp* on your system, start by selecting a site name (less than 8 characters). A *uucp* account must be created in the password file and a password set up. Then, create the appropriate spooling directories with mode 755 and owned by user *uucp*, group *daemon*.

If you have an auto-call unit, the L.sys, L-dialcodes, and L-devices files should be created. The L.sys file should contain the phone numbers and login sequences required to establish a connection with a *uucp* daemon on another machine. For example, our L.sys file looks something like:

```
adiron Any ACU 1200 out0123456789- ogin-EOT-ogin uucp
cbosg Never Slave 300
cbosgd Never Slave 300
chico Never Slave 1200 out2010123456
```

The first field is the name of a site, the second indicates when the machine may be called, the third field specifies how the host is connected (through an ACU, a hardwired line, etc.), then comes the phone number to use in connecting through an auto-call unit, and finally a login sequence. The phone number may contain common abbreviations which are defined in the L-dialcodes file. The device specification should refer to devices specified in the L-devices file. Indicating only ACU causes the *uucp* daemon, *uucico*, to search for any available auto-call unit in L-devices. Our L-dialcodes file is of the form:

```
ucb 2
out 9%
```

while our L-devices file is:

```
ACU cul0 unused 1200 ventel
```

Refer to the README file in the *uucp* source directory for more information about installation.

As *uucp* operates it creates (and removes) many small files in the directories underneath */usr/spool/uucp*. Sometimes files are left undeleted; these are most easily purged with the *uuclean* program. The log files can grow without bound unless trimmed back; *uulog* is used to maintain these files. Many useful aids in maintaining your *uucp* installation are included in a subdirectory UUAIDS beneath */usr/src/usr.bin/uucp*. Peruse this directory and read the “setup” instructions also located there.

5. NETWORK SETUP

4.2BSD provides support for the DARPA standard Internet protocols IP, ICMP, TCP, and UDP. These protocols may be used on top of a variety of hardware devices ranging from the IMP's used in the ARPANET to local area network controllers for the Ethernet. Network services are split between the kernel (communication protocols) and user programs (user services such as TELNET and FTP). This section describes how to configure your system to use the networking support.

5.1. System configuration

To configure the kernel to include the Internet communication protocols, define the INET option and include the pseudo-devices "inet", "pty", and "loop" in your machine's configuration file. The "pty" pseudo-device forces the pseudo terminal device driver to be configured into the system, see *pty*(4), while the "loop" pseudo-device forces inclusion of the software loopback interface driver. The loop driver is used in network testing and also by the mail system.

If you are planning to use the network facilities on a 10Mb/s Ethernet, the pseudo-device "ether" should also be included in the configuration; this forces inclusion of the Address Resolution Protocol module used in mapping between 48-bit Ethernet and 32-bit Internet addresses. Also, if you have an imp, you will need to include the pseudo-device "imp."

Before configuring the appropriate networking hardware, you should consult the manual pages in section 4 of the programmer's manual. The following table lists the devices for which software support exists.

11.	Device name	Manufacturer and product
	acc	ACC LH/DH interface to IMP
	css	DEC IMP-11A interface to IMP
	dmc	DEC DMC-11 (also works with DMR-11)
	ec	3Com 10Mb/s Ethernet
	en	Xerox 3Mb/s prototype Ethernet (not a product)
	hy	NSC Hyperchannel, w/ DR-11B and PI-13 interfaces
	il	Interlan 10Mb/s Ethernet
	pcl	DEC PCL-11
	un	Ungermann-Bass network w/ DR-11W interface
	vv	Proteon ring network (V2LNI)

All network interface drivers require some or all of their host address be defined at boot time. This is accomplished with *ifconfig*(8C) commands included in the */etc/rc.local* file. Interfaces which are able to dynamically deduce the host part of an address, but not the network number, take the network number from the address specified with *ifconfig*. Hosts which use a more complex address mapping scheme, such as the Address Resolution Protocol, *arp*(4), require the full address. The manual page for each network interface describes the method used to establish a host's address. *Ifconfig*(8) can also be used to set options for the interface at boot time. These options include disabling the use of the Address Resolution Protocol and/or the use of trailer encapsulation; this is useful if a network is shared with hosts running software which is unable to perform these functions. Options are set independently for each interface, and apply to all packets sent using that interface. An alternative approach to ARP is to divide the address range, using ARP only for those addresses below the cutoff and using another mapping above this constant address; see the source (*/sys/netinet/if_ether.c*) for more information.

In order to use the pseudo terminals just configured, device entries must be created in the */dev* directory. To create 16 pseudo terminals (plenty, unless you have a heavy network load) perform the following commands.

```
# cd /dev
# MAKEDEV pty0
```

More pseudo terminals may be made by specifying *pty1*, *pty2*, etc. The kernel normally includes support for 32 pseudo terminals unless the configuration file specifies a different number. Each pseudo terminal actually consists of two files in */dev*: a master and a slave. The master pseudo terminal file is named */dev/pty?*, while the slave side is */dev/ttyp?*. Pseudo terminals are also used by the *script*(1) program. In addition to creating the pseudo terminals, be sure to install them in the */etc/ttys* file (with a '0' in the first column so no *getty* is started), and in the */etc/ttytype* file (with type "network").

When configuring multiple networks some thought must be given to the ordering of the devices in the configuration file. The first network interface configured in the system is used as the default network when the system is forced to assign a local address to a socket. This means that your most widely known network should always be placed first in the configuration file. For example, hosts attached to both the ARPANET and our local area network have devices configured in the order show below.

```
device      acc0      at uba? csr 0167600 vector accrint accxint
device      en0      at uba? csr 0161000 vector enxint enrint encollide
```

5.2. Network data bases

A number of data files are used by the network library routines and server programs. Most of these files are host independent and updated only rarely.

```
111.
File   Manual reference Use
-----
/etc/hosts   hosts(5)   host names
/etc/networks networks(5) network names
/etc/services services(5) list of known services
/etc/protocols protocols(5) protocol names
/etc/hosts.equiv rshd(8C) list of "trusted" hosts
/etc/rc.local rc(8) command script for starting servers
/etc/ftpusers ftpd(8C) list of "unwelcome" ftp users
```

The files distributed are set up for ARPANET or other Internet hosts. Local networks and hosts should be added to describe the local configuration; the Berkeley entries may serve as examples (see also the next section). Network numbers will have to be chosen for each ethernet. For sites not connected to the Internet, these can be chosen more or less arbitrarily, otherwise the normal channels should be used for allocation of network numbers.

5.2.1. Regenerating */etc/hosts* and */etc/networks*

The host and network name data bases are normally derived from a file retrieved from the Internet Network Information Center at SRI. To do this you should use the program */etc/gettable* to retrieve the NIC host data base, and the program */etc/htable* to convert it to the format used by the libraries.

```
# cd /usr/src/ucb/netser/htable
# /etc/gettable sri-nic
Connection to sri-nic opened.
Host table received.
Connection to sri-nic closed.
# /etc/htable hosts.txt
Warning, no localgateways file.
#
```

The *htable* program generates two files of interest in the local directory: *hosts* and *networks*. If a file "localhosts" is present in the working directory its contents are first copied to the output file. Similarly, a

“localnetworks” file may be prepended to the output created by *htable*. It is usually wise to run *diff(1)* on the new host and network data bases before installing them in */etc*.

5.2.2. */etc/hosts.equiv*

The remote login and shell servers use an authentication scheme based on trusted hosts. The *hosts.equiv* file contains a list of hosts which are considered trusted and/or, under a single administrative control. When a user contacts a remote login or shell server requesting service, the client process passes the user's name and the official name of the host on which the client is located. In the simple case, if the hosts's name is located in *hosts.equiv* and the user has an account on the server's machine, then service is rendered (i.e. the user is allowed to log in, or the command is executed). Users may constrain this “equivalence” of machines by installing a *.rhosts* file in their login directory. The root login is handled specially, bypassing the *hosts.equiv* file, and using only the */.rhosts* file.

Thus, to create a class of equivalent machines, the *hosts.equiv* file should contain the *official* names for those machines. For example, most machines on our major local network are considered trusted, so the *hosts.equiv* file is of the form:

```
ucbarpa
ucbcaldcr
ucbdali
ucbernie
ucbkim
ucbmatisse
ucbmonet
ucbvax
ucbmiro
ucbdegas
```

5.2.3. */etc/rc.local*

Most network servers are automatically started up at boot time by the command file */etc/rc* (if they are installed in their presumed locations). These include the following:

```
11.
/etc/rshd   shell server
/etc/rexecd exec server
/etc/rlogind login server
/etc/rwhod  system status daemon
```

To have other network servers started up as well, commands of the following sort should be placed in the site dependent file */etc/rc.local*.

```
if [ -f /etc/telnetd ]; then
    /etc/telnetd & echo -n ' telnetd'          >/dev/console
fi
```

The following servers are included with the system and should be installed in */etc/rc.local* as the need arises.

```

11.
/etc/telnetd  TELNET server
/etc/ftpd    FTP server
/etc/tftpd   TFTP server
/etc/syslog  error logging server
/etc/sendmail SMTP server
/etc/courierd Courier remote procedure call server
/etc/routed  routing table management daemon

```

Consult the manual pages and accompanying documentation (particularly for sendmail) for details about their operation.

5.2.4. /etc/ftusers

The FTP server included in the system provides support for an anonymous FTP account. Due to the inherent security problems with such a facility you should read this section carefully if you consider providing such a service.

An anonymous account is enabled by creating a user *ftp*. When a client uses the anonymous account a *chroot(2)* system call is performed by the server to restrict the client from moving outside that part of the file system where the user *ftp* home directory is located. Because a *chroot* call is used, certain programs and files must be supplied the server process for it to execute properly. Further, one must be sure that all directories and executable images are unwritable. The following directory setup is recommended.

```

# cd ~ftp
# chmod 555 .; chown ftp .; chgrp ftp .
# mkdir bin etc pub
# chown root bin etc
# chmod 555 bin etc
# chown ftp pub
# chmod 777 pub
# cd bin
# cp /bin/sh /bin/ls .
# chmod 111 sh ls
# cd ../etc
# cp /etc/passwd /etc/group .
# chmod 444 passwd group

```

When local users wish to place files in the anonymous area, they must be placed in a subdirectory. In the setup here, the directory *~ftp/pub* is used.

Aside from the problems of directory modes and such, the *ftp* server may provide a loophole for interlopers if certain user accounts are allowed. The file */etc/ftusers* is checked on each connection. If the requested user name is located in the file, the request for service is denied. This file normally has the following names on our systems.

```

uucp
root

```

Accounts with nonstandard shells and no passwords (e.g., *who* or *finger*) should also be listed in this file to prevent their use as anonymous accounts with *ftp*.

5.3. Routing and gateways/bridges

If your environment allows access to networks not directly attached to your host you will need to set up routing information to allow packets to be properly routed. Two schemes are supported by the system. The first scheme employs the routing table management daemon */etc/routed* to maintain the system routing tables. The routing daemon uses a variant of the Xerox Routing Information Protocol to maintain up to date routing tables in a cluster of local area networks. By using the */etc/gateways* file created by */etc/htable*,

the routing daemon can also be used to initialize static routes to distant networks. When the routing daemon is started up (usually from `/etc/rc.local`) it reads `/etc/gateways` and installs those routes defined there, then broadcasts on each local network to which the host is attached to find other instances of the routing daemon. If any responses are received, the routing daemons cooperate in maintaining a globally consistent view of routing in the local environment. This view can be extended to include remote sites also running the routing daemon by setting up suitable entries in `/etc/gateways`; consult *routed*(8C) for a more thorough discussion.

The second approach is to define a wildcard route to a smart gateway and depend on the gateway to provide ICMP routing redirect information to dynamically create a routing data base. This is done by adding an entry of the form

```
/etc/route add 0 smart-gateway 1
```

to `/etc/rc.local`; see *route*(8C) for more information. The wildcard route, indicated by a 0 valued destination, will be used by the system as a “last resort” in routing packets to their destination. Assuming the gateway to which packets are directed is able to generate the proper routing redirect messages, the system will then add routing table entries based on the information supplied. This approach has certain advantages over the routing daemon, but is unsuitable in an environment where there are only bridges (i.e. pseudo gateways which, for instance, do not generate routing redirect messages). Further, if the smart gateway goes down there is no alternative, save manual alteration of the routing table entry, to maintaining service.

The system always listens, and processes, routing table redirect information, so it is possible to combine both the above facilities. For example, the routing table management process might be used to maintain up to date information about routes to geographically local networks, while employing the wildcard routing techniques for “distant” networks. The *netstat*(1) program may be used to display routing table contents as well as various routing oriented statistics. For example,

```
#netstat -r
```

will display the contents of the routing tables, while

```
#netstat -r -s
```

will show the number of routing table entries dynamically created as a result of routing redirect messages, etc.

6. SYSTEM OPERATION

This section describes procedures used to operate a VAX UNIX system. Procedures described here are used periodically, to reboot the system, analyze error messages from devices, do disk backups, monitor system performance, recompile system software and control local changes.

6.1. Bootstrap and shutdown procedures

In a normal reboot, the system checks the disks and comes up multi-user without intervention at the console. Such a reboot can be stopped (after it prints the date) with a ^C (interrupt). This will leave the system in single-user mode, with only the console terminal active.

If booting from the console command level is needed, then the command

```
>>> B
```

will boot from the default device. On an 11/780 (11/730) the default device is determined by a "DEPOSIT" command stored on the floppy (cassette) in the file "DEFBOO.CMD"; on an 11/750 the default device is determined by the setting of a switch on the front panel.

You can boot a system up single user on a 780 or 730 by doing

```
>>> B XX S
```

where XX is one of HP, HK, UP, RA, or RB for a 730. The corresponding command on an 11/750 is

```
>>> B/1
```

For second vendor storage modules on the UNIBUS or MASSBUS of an 11/750 you will need to have a boot prom. Most vendors will sell you such proms for their controllers; contact your vendor if you don't have one.

Other possibilities are:

```
>>> B ANY
```

or, on a 750

```
>>> B/3
```

These commands boot and ask for the name of the system to be booted. They can be used after building a new test system to give the boot program the name of the test version of the system.

To bring the system up to a multi-user configuration from the single-user status after, e.g., a "B HPS" on an 11/780, "B RBS" on a 730, or a "B/1" on an 11/750 all you have to do is hit ^D on the console. The system will then execute /etc/rc, a multi-user restart script (and /etc/rc.local), and come up on the terminals listed as active in the file /etc/ttyS. See *init*(8) and *ttyS*(5). Note, however, that this does not cause a file system check to be performed. Unless the system was taken down cleanly, you should run "fsck -p" or force a reboot with *reboot*(8) to have the disks checked.

To take the system down to a single user state you can use

```
# kill 1
```

or use the *shutdown*(8) command (which is much more polite, if there are other users logged in.) when you are up multi-user. Either command will kill all processes and give you a shell on the console, as if you had just booted. File systems remain mounted after the system is taken single-user. If you wish to come up multi-user again, you should do this by:

```
# cd /
# /etc/umount -a
# ^D
```

Each system shutdown, crash, processor halt and reboot is recorded in the file `/usr/adm/shutdownlog` with the cause.

6.2. Device errors and diagnostics

When errors occur on peripherals or in the system, the system prints a warning diagnostic on the console. These messages are collected regularly and written into a system error log file `/usr/adm/messages`.

Error messages printed by the devices in the system are described with the drivers for the devices in section 4 of the programmer's manual. If errors occur indicating hardware problems, you should contact your hardware support group or field service. It is a good idea to examine the error log file regularly (e.g. with `tail -r /usr/adm/messages`).

6.3. File system checks, backups and disaster recovery

Periodically (say every week or so in the absence of any problems) and always (usually automatically) after a crash, all the file systems should be checked for consistency by `fsck` (1). The procedures of `reboot` (8) should be used to get the system to a state where a file system check can be performed manually or automatically.

Dumping of the file systems should be done regularly, since once the system is going it is easy to become complacent. Complete and incremental dumps are easily done with `dump` (8). You should arrange to do a towers-of-hanoi dump sequence; we tune ours so that almost all files are dumped on two tapes and kept for at least a week in most every case. We take full dumps every month (and keep these indefinitely). Operators can execute `"dump w"` at login that will tell them what needs to be dumped (based on the `/etc/fstab` information). Be sure to create a group **operator** in the file `/etc/group` so that `dump` can notify logged-in operators when it needs help.

More precisely, we have three sets of dump tapes: 10 daily tapes, 5 weekly sets of 2 tapes, and fresh sets of three tapes monthly. We do daily dumps circularly on the daily tapes with sequence `'3 2 5 4 7 6 9 8 9 9 9 ...'`. Each weekly is a level 1 and the daily dump sequence level restarts after each weekly dump. Full dumps are level 0 and the daily sequence restarts after each full dump also.

Thus a typical dump sequence would be:

```
center; c c c c n n n l l. tape name level number date opr size _ FULL 0 Nov 24,
1979 jkf 137K D1 3 Nov 28, 1979 jkf 29K D2 2 Nov 29, 1979 rrh 34K
D3 5 Nov 30, 1979 rrh 19K D4 4 Dec 1, 1979rrh 22K W1 1 Dec 2,
1979etc 40K D5 3 Dec 4, 1979rrh 15K D6 2 Dec 5, 1979jkf 25K D7 5 Dec 6,
1979jkf 15K D8 4 Dec 7, 1979rrh 19K W2 1 Dec 9, 1979etc 118K D9 3 Dec
11, 1979 rrh 15K D10 2 Dec 12, 1979 rrh 26K D1 5 Dec 15,
1979 rrh 14K W3 1 Dec 17, 1979 etc 71K D2 3 Dec 18, 1979 etc 13K
FULL 0 Dec 22, 1979 etc 135K
```

We do weekly's often enough that daily's always fit on one tape and never get to the sequence of 9's in the daily level numbers.

Dumping of files by name is best done by `tar` (1) but the amount of data that can be moved in this way is limited to a single tape. Finally if there are enough drives entire disks can be copied with `dd` (1) using the raw special files and an appropriate blocking factor; the number of sectors per track is usually a good value to use, consult `/etc/disktab`.

It is desirable that full dumps of the root file system be made regularly. This is especially true when only one disk is available. Then, if the root file system is damaged by a hardware or software failure, you can rebuild a workable disk doing a restore in the same way that the initial root file system was created.

Exhaustion of user-file space is certain to occur now and then; disk quotas may be imposed, or if you prefer a less facist approach, try using the programs `du` (1), `df` (1), `quot` (8), combined with threatening messages of the day, and personal letters.

6.4. Moving filesystem data

If you have the equipment, the best way to move a file system is to dump it to magtape using *dump* (8), use *newfs* (8) to create the new file system, and restore the tape, using *restore* (8). If for some reason you don't want to use magtape, *dump* accepts an argument telling where to put the dump; you might use another disk. The restore program uses an "in-place" algorithm which allows file system dumps to be restored without concern for the original size of the file system. Further, portions of a file system may be selectively restored in a manner similar to the tape archive program.

If you have to merge a file system into another, existing one, the best bet is to use *tar* (1). If you must shrink a file system, the best bet is to dump the original and restore it onto the new file system. If you are playing with the root file system and only have one drive, the procedure is more complicated. What you do is the following:

1. GET A SECOND PACK!!!!
2. Dump the root file system to tape using *dump* (8).
3. Bring the system down and mount the new pack.
4. Load the distribution tape and install the new root file system as you did when first installing the system.
5. Boot normally using the newly created disk file system.

Note that if you change the disk partition tables or add new disk drivers they should also be added to the standalone system in */sys/stand* and the default disk partition tables in */etc/disktab* should be modified.

6.5. Monitoring System Performance

The *vmstat* program provided with the system is designed to be an aid to monitoring systemwide activity. Together with the *ps* (1) command (as in "ps av"), it can be used to investigate systemwide virtual memory activity. By running *vmstat* when the system is active you can judge the system activity in several dimensions: job distribution, virtual memory load, paging and swapping activity, disk and cpu utilization. Ideally, there should be few blocked (b) jobs, there should be little paging or swapping activity, there should be available bandwidth on the disk devices (most single arms peak out at 30-35 tps in practice), and the user cpu utilization (us) should be high (above 60%).

If the system is busy, then the count of active jobs may be large, and several of these jobs may often be blocked (b). If the virtual memory is active, then the paging demon will be running (sr will be non-zero). It is healthy for the paging demon to free pages when the virtual memory gets active; it is triggered by the amount of free memory dropping below a threshold and increases its pace as free memory goes to zero.

If you run *vmstat* when the system is busy (a "vmstat 1" gives all the numbers computed by the system), you can find imbalances by noting abnormal job distributions. If many processes are blocked (b), then the disk subsystem is overloaded or imbalanced. If you have a several non-dma devices or open teletype lines that are "ringing", or user programs that are doing high-speed non-buffered input/output, then the system time may go high (60-70% or higher). It is often possible to pin down the cause of high system time by looking to see if there is excessive context switching (cs), interrupt activity (in) or system call activity (sy). Cumulatively on one of our large machines we average about 60 context switches and interrupts per second and about 90 system calls per second.

If the system is heavily loaded, or if you have little memory for your load (1M is little in most any case), then the system may be forced to swap. This is likely to be accompanied by a noticeable reduction in system performance and pregnant pauses when interactive jobs such as editors swap out. If you expect to be in a memory-poor environment for an extended period you might consider administratively limiting system load.

6.6. Recompiling and reinstalling system software

It is easy to regenerate the system, and it is a good idea to try rebuilding pieces of the system to build confidence in the procedures. The system consists of two major parts: the kernel itself (*/sys*) and the user programs (*/usr/src* and subdirectories). The major part of this is */usr/src*.

The three major libraries are the C library in `/usr/src/lib/libc` and the FORTRAN libraries `/usr/src/usr.lib/libI77` and `/usr/src/usr.lib/libF77`. In each case the library is remade by changing into the corresponding directory and doing

```
# make
```

and then installed by

```
# make install
```

Similar to the system,

```
# make clean
```

cleans up.

The source for all other libraries is kept in subdirectories of `/usr/src/usr.lib`; each has a makefile and can be recompiled by the above recipe.

If you look at `/usr/src/Makefile`, you will see that you can recompile the entire system source with one command. To recompile a specific program, find out where the source resides with the `whereis(1)` command, then change to that directory and remake it with the makefile present in the directory. For instance, to recompile “date”, all one has to do is

```
# whereis date
date: /usr/src/bin/date.c /bin/date /usr/man/man1/date.1
# cd /usr/src/bin
# make date
```

this will create an unstripped version of the binary of “date” in the current directory. To install the binary image, use the install command as in

```
# install -s date /bin/date
```

The `-s` option will insure the installed version of date has its symbol table stripped. The install command should be used instead of `mv` or `cp` as it understands how to install programs even when the program is currently in use.

If you wish to recompile and install all programs in a particular target area you can override the default target by doing:

```
# make
# make DESTDIR=pathname install
```

To regenerate all the system source you can do

```
# cd /usr/src
# make
```

If you modify the C library, say to change a system call, and want to rebuild and install everything from scratch you have to be a little careful. You must insure the libraries are installed before the remainder of the source, otherwise the loaded images will not contain the new routine from the library. The following steps are recommended.

```
# cd /usr/src
# cd lib; make install
# cd ..
# make usr.lib
# cd usr.lib; make install
# cd ..
# make bin etc usr.bin ucb games local
# for i in bin etc usr.bin ucb games local; do (cd $i; make install); done
```

This will take about 12 hours on a reasonably configured 11/750.

6.7. Making local modifications

To keep track of changes to system source we migrate changed versions of commands in `/usr/src/bin`, `/usr/src/usr.bin`, and `/usr/src/ucb` in through the directory `/usr/src/new` and out of the original directory into `/usr/src/old` for a time before removing them. Locally written commands that aren't distributed are kept in `/usr/src/local` and their binaries are kept in `/usr/local`. This allows `/usr/bin`, `/usr/ucb`, and `/bin` to correspond to the distribution tape (and to the manuals that people can buy). People wishing to use `/usr/local` commands are made aware that they aren't in the base manual. As manual updates incorporate these commands they are moved to `/usr/ucb`.

A directory `/usr/junk` to throw garbage into, as well as binary directories `/usr/old` and `/usr/new` are useful. The `man` command supports manual directories such as `/usr/man/manj` for junk and `/usr/man/manl` for local to make this or something similar practical.

6.8. Accounting

UNIX optionally records two kinds of accounting information: connect time accounting and process resource accounting. The connect time accounting information is stored in the file `/usr/adm/wtmp`, which is summarized by the program `ac`(8). The process time accounting information is stored in the file `/usr/adm/acct`, and analyzed and summarized by the program `sa`(8).

If you need to implement recharge for computing time, you can implement procedures based on the information provided by these commands. A convenient way to do this is to give commands to the clock daemon `/etc/cron` to be executed every day at a specified time. This is done by adding lines to `/usr/adm/crontab`; see `cron`(8) for details.

6.9. Resource control

Resource control in the current version of UNIX is fairly elaborate compared to most UNIX systems. The disc quota facilities developed at the University of Melbourne have been incorporated in the system and allow control over the number of files and amount of disc space each user may use on each file system. In addition, the resources consumed by any single process can be limited by the mechanisms of `setrlimit`(2). As distributed, the latter mechanism is voluntary, though sites may choose to modify the login mechanism to impose limits not covered with disc quotas.

To utilize the disc quota facilities, the system must be configured with "options QUOTA". File systems may then be placed under the quota mechanism by creating a null file `quotas` at the root of the file system, running `quotacheck`(8), and modifying `/etc/fstab` to indicate the file system is read-write with disc quotas (a "rq" type field). The `quotaon`(8) program may then be run to enable quotas.

Individual quotas are applied by using the quota editor `edquota`(8). Users may view their quotas (but not those of other users) with the `quota`(1) program. The `repquota`(8) program may be used to summarize the quotas and current space usage on a particular file system or file systems.

Quotas are enforced with *soft* and *hard* limits. When a user first reaches a soft limit on a resource, a message is generated on his/her terminal. If the user fails to lower the resource usage below the soft limit the next time they log in to the system the `login` program will generate a warning about excessive usage. Should three login sessions go by with the soft limit breached the system then treats the soft limit as a *hard* limit and disallows any allocations until enough space is reclaimed to bring the user back below the soft limit. Hard limits are enforced strictly resulting in errors when a user tries to create or write a file. Each time a hard limit is exceeded the system will generate a message on the user's terminal.

Consult the auxiliary document, "Disc Quotas in a UNIX Environment" and the appropriate manual entries for more information.

6.10. Network troubleshooting

If you have anything more than a trivial network configuration, from time to time you are bound to run into problems. Before blaming the software, first check your network connections. On networks such as the Ethernet a loose cable tap or misplaced power cable can result in severely deteriorated service. The `netstat`(1) program may be of aid in tracking down hardware malfunctions. In particular, look at the `-i` and

–s options in the manual page.

Should you believe a communication protocol problem exists, consult the protocol specifications and attempt to isolate the problem in a packet trace. The `SO_DEBUG` option may be supplied before establishing a connection on a socket, in which case the system will trace all traffic and internal actions (such as timers expiring) in a circular trace buffer. This buffer may then be printed out with the `trpt(8C)` program. Most all the servers distributed with the system accept a `-d` option forcing all sockets to be created with debugging turned on. Consult the appropriate manual pages for more information.

6.11. Files which need periodic attention

We conclude the discussion of system operations by listing the files that require periodic attention or are system specific

center; lb a. `/etc/fstab` how disk partitions are used `/etc/disktab` disk partition sizes `/etc/printcap` printer data base `/etc/gettytab` terminal type definitions `/etc/remote` names and phone numbers of remote machines for `tip(1)` `/etc/group` group memberships `/etc/motd` message of the day `/etc/passwd` password file; each account has a line `/etc/rc.local` local system restart script; runs reboot; starts daemons `/etc/hosts` host name data base `/etc/networks` network name data base `/etc/services` network services data base `/etc/hosts.equiv` hosts under same administrative control `/etc/securetty` restricted list of ttys where root can log in `/etc/ttys` enables/disables ports `/etc/ttytype` terminal types connected to ports `/usr/lib/crontab` commands that are run periodically `/usr/lib/aliases` mail forwarding and distribution groups `/usr/adm/acct` raw process account data `/usr/adm/messages` system error log `/usr/adm/shutdownlog` log of system reboots `/usr/adm/wtmp` login session accounting

APPENDIX A – BOOTSTRAP DETAILS

This appendix contains pertinent files and numbers regarding the bootstrapping procedure for 4.2BSD. You should never have to look at this appendix. However, if there are problems in installing the distribution on your machine, the material contained here may prove useful.

Contents of the distribution tapes

The distribution normally consists of two 1600bpi 2400' magnetic tapes. The first tape contains the following files on it. All tape files are blocked in 10 kilobytes records, except for the first file on the first tape which has 512 byte records.

111.

Tape file	Records*	Contents
—		
one	194	8 bootstrap monitor programs and a <i>tp</i> (1) file containing <i>boot</i> , <i>format</i> , and <i>copy</i>
two	205	“mini root” file system
three	380	<i>dump</i> (8) of distribution root file system
four	440	<i>tar</i> (1) image of /sys, including GENERIC system
five	2111	<i>tar</i> (1) image of binaries and libraries in /usr
six	576	<i>tar</i> (1) image of /usr/lib/vfont

The second tape contains the following files.

111.

Tape file	# Records	Contents
—		
one	2100	<i>tar</i> (1) image of /usr/src
two	973	<i>tar</i> (1) image of user contributed software
three	420	<i>tar</i> (1) image of /usr/ingres

The distribution tape is made with the shell scripts located in the directory /sys/dist. To construct a distribution tape one must first build a mini root file system with the *buildmini* shell script.

```
#!/bin/sh
#   @(#)buildmini  4.4  7/9/83
#
miniroot=hp0g
minitype=rm80
#
date
umount /dev/${miniroot}
newfs -s 4096 ${miniroot} ${minitype}
fsck /dev/r${miniroot}
mount /dev/${miniroot} /mnt
cd /mnt; sh /sys/dist/get
cd /sys/dist; sync
umount /dev/${miniroot}
fsck /dev/${miniroot}
date
```

* The number of records in each tape file may not be precisely that shown in this table; these values reflect the contents of the distribution tape at the time this document was written.

The *buildmini* script uses the *get* script to construct the actual file system.

```

#!/bin/sh
#   @(#)get    4.13  7/19/83
#
# Shell script to build a mini-root file system
# in preparation for building a distribution tape.
# The file system created here is image copied onto
# tape, then image copied onto disk as the "first"
# step in a cold boot of 4.2 systems.
#

```

Summarizing then, to construct a distribution tape you can use the above scripts and the following commands.

```
# buildmini
# maketape
...
Done, rewinding first tape
Mount second tape and hit return when ready
(remove the first tape and place a fresh one on the drive)
...
Done, rewinding second tape
```

Control status register addresses

The distribution uses many standalone device drivers which presume the location of a UNIBUS device's control status register (CSR). The following table summarizes these values.

```
111.
Device name      Controller  CSR address (octal)
-
ra  DEC UDA50    0172150
rb  DEC 730 IDC  0175606
rk  DEC RK11    0177440
rl  DEC RL11    0174400
tm  EMULEX TC-11 0172520
ts  DEC TS11    0172520
up  EMULEX SC-21V 0176700
ut  SI 9700     0172440
```

All MASSBUS controllers are located at standard offsets from the base address of the MASSBUS adapter register bank.

Generic system control status register addresses

The *generic* version of the operating system supplied with the distribution contains the UNIBUS devices indicated below. These devices will be recognized if the appropriate control status registers respond at any of the indicated UNIBUS addresses.

```
111.
Device name      Controller  CSR addresses (octal)
-
hk  DEC RK11    0177440
tm  EMULEX TC-11 0172520
ut  SI 9700     0172440
up  EMULEX SC-21V 0176700, 0174400, 0176300
ra  DEC UDA-50  0172150, 0172550, 0177550
rb  DEC 730 IDC  0175606
rl  DEC RL11    0174400
dn  DEC DN11    0160020
dm  DM11 equivalent 0170500
dh  DH11 equivalent 0160040
dz  DEC DZ11    0160100, 0160110, ... 0160170
ts  DEC TS11    0172520
dmf DEC DMF32   0160340
lp  DEC LP11    0177514
```

If devices other than the above are located at any of the addresses indicated, the system may not bootstrap properly.

APPENDIX B – LOADING THE TAPE MONITOR

This section indicates how the bootstrap monitor located on the first tape of the distribution tape set may be loaded. This should not be necessary, but has been included as a fallback measure in case it is not possible to read the distributed console medium. **WARNING:** the bootstraps supplied below may not work, in certain instances on an 11/730 because they use a buffered data path for transferring data from tape to memory; consult our group if you are unable to load the monitor on an 11/730.

To load the tape bootstrap monitor, first mount the magnetic tape on drive 0 at load point, making sure that the write ring is not inserted. Temporarily set the reboot switch on an 11/780 or 11/730 to off; on an 11/750 set the power-on action to halt. (In normal operation an 11/780 or 11/730 will have the reboot switch on, and an 11/750 will have the power-on action set to boot/restart.)

If you have an 11/780 give the commands:

```
>>> HALT
>>> UNJAM
```

Then, on any machine, give the init command:

```
>>> I
```

and then key in at location 200 and execute either the TS, HT, TM, or MT bootstrap that follows, as appropriate. The machine's printouts are shown in boldface, explanatory comments are within (). (You can use 'delete' to delete a character and 'control U' to kill the whole line.)

>>> D + AAD408AB
>>> D + 8FD00C
>>> D + CA800000
>>> D + 8F320800
>>> D + 10AAFE00
>>> D + 2008F3C
>>> D + ABD014AB
>>> D + FE15044
>>> D + 399AF850
>>> D + 6B

```

(The next two deposits set up the addresses of the MASSBUS)
(adapter and the drive number for the tape formatter)
(the 20012000 here is the address of the 11/780 mba1 and the 0)
(reflects that the formatter is drive 0 on mba1)

```

>>> D + 20012000
>>> D + 0
>>> S 200
>>> S 200
>>> S 200
>>> S 200

```

(no toggle-in code exists for the UT device)

If the tape doesn't move the first time you start the bootstrap program with "S 200" you probably have entered the program incorrectly (but also check that the tape is online). Start over and check your typing. For the HT, MT, and TM bootstraps you will not be able to see the tape motion as you advance through the first few blocks as the tape motion is all within the vacuum columns.

Next, deposit in RA the address of the tape MBA/UBA and in RB the address of the device registers or unit number from one of:

```

lw(1.5i) l.
>>> D/G A 20006000 (for tapes on 780 uba0)
>>> D/G A 20008000 (for tapes on 780 uba1)
>>> D/G A 20012000 (for tapes on 780 mba1)
>>> D/G A 20010000 (for tapes on 780 mba0)
>>> D/G A F30000 (for tapes on 750 uba0)
>>> D/G A F2A000 (for tapes on 750 mba1)
>>> D/G A F28000 (for tapes on 750 mba0)
>>> D/G A F26000 (for tapes on 730 uba0)

```

and for register B:

```
lw(1.5i) l.  
>>>D/G B 0      (for tm03/tm78 formatters at mba? drive 0)  
>>>D/G B 1      (for tm03/tm78 formatters at mba? drive 1)  
>>>D/G B 2013F550 (for tm11/ts11/tu80 tapes on 780 uba0)  
>>>D/G B FFF550  (for tm11/ts11/tu80 tapes on 750 or 730 uba0)
```

Then start the bootstrap program with

```
>>>S 0
```

The console should type

```
=
```

You are now talking to the tape bootstrap monitor. At any point in the following procedure you can return to this section, reload the tape bootstrap, and restart the procedure. The console monitor is identical to that loaded from a TU58 console cassette, follow the instructions in section 2 as they apply to this device. The only exception is that when using programs loaded from the tape bootstrap monitor, programs will always return to the monitor (the “=” prompt). This saves your having to type in the above toggle-in code for each program to be loaded.

APPENDIX C – INSTALLATION TROUBLESHOOTING

This appendix lists and explains certain problems which might be encountered while trying to install the 4.2BSD distribution. The information provided here is limited to the early steps in the installation process; i.e. up to the point where the root file system is installed. If you have a problem installing the release consult this section for an indication of the problem before contacting our group.

Using the distribution console medium.

This section describes problems which may occur when using the programs provided on the distributed console medium: TU58 cassette or RX01 floppy disk.

program can not be loaded.

Check to make sure the correct floppy or cassette is being used. If using a floppy, be sure it is not in upside down. If using a cassette on an 11/730, be certain drive 0 is being used. If a hard i/o error occurred while reading a floppy, try resetting the console LSI-11 by powering it on and off. If you can not boot the cassette's bootstrap monitor, verify the standard DEC console cassette can be read; if it can not, your cassette is broken – not uncommon.

program halts without warning.

Check to make sure you have specified the correct disk to format; consult sections 1.3 and 1.4 for a discussion of the VAX and UNIX device naming conventions. On 11/750's, specifying a non-existent MASSBUS device will cause the program to halt as it receives an interrupt (standalone programs operate by polling devices).

If using a floppy, try reading the floppy under your current system. If this works, copy the floppy to a new one and begin again. If using a cassette on an 11/730, do likewise.

format prints "Known devices are ...".

You have requested *format* to work on a device for which it has no driver, or which does not exist; only the indicated devices are supported.

format, boot, or copy prints "unknown drive type".

A MASSBUS disk was specified, but the associated MASSBUS drive type register indicates a drive of unknown type. This probably means you typed something wrong or your hardware is incorrectly configured.

format, boot, or copy prints "unknown device".

The device specified is probably not one of those supported by the distribution; consult section 1.1. If the device is listed in section 1.1, the drive may be dual-ported, or for some other reason the driver was unable to decipher its characteristics. If this is a MASSBUS drive, try powering the MASSBUS adapter and/or controller on and off to clear the drive type register.

copy does not copy 205 records

If a tape read error occurred, clean your tape drive heads. If a disk write error occurred, the disk formatting may have failed. If the disk pack is removable, try another one. If you are currently running UNIX, you can reboot your old system and use *dd* to copy the mini-root file system into a disk partition (assuming the destination is not in use by the running system).

boot prints "not a directory"

The *boot* program was unable to find the requested program because it encountered something other than a directory while searching the file system. This usually indicates no file system is present on the disk partition supplied, or the file system has been corrupted. First check to make sure you typed the correct line to boot. If this is the case and you are booting off the mini-root file system, the mini-root was probably not copied correctly off the tape (perhaps it was not placed in the correct disk partition). Try reinstalling the mini-root file system or, if trying to boot the true root file system, try booting off the mini-root file system and run *fsck* on the restored root file system to insure its integrity. Finally, as a last resort, copy the *boot*

program from the mini-root file system to the newly installed root file system.

boot prints "bad format"

The program you requested *boot* to load did not have a 407, 410, or 413 magic number in its header. This should never happen on a distribution system. If you were trying to boot off the root file system, reboot the system on the mini-root file system and look at the program on the root file system. Try copying the copy of *vmunix* on the mini-root to the root file system also.

boot prints "read short"

The file header for the program indicated a size larger than the actual size of the file located on disk. This is probably the result of file system corruption (or a disk i/o error). Try booting again or creating a new copy of the program to be loaded (see above).

Booting the generic system

This section contains common problems encountered when booting the generic version of the system.

system panics with "panic: iinit"

This occurred because the system was unable to locate the program */etc/init*. The root file system supplied at the "root device?" prompt was probably incorrect. Remember that when running on the mini-root file system, this question must be answered with something of the form "hp0*". If the answer had been "hp0", the system would have used the "a" partition on unit 0 of the "hp" drive, where presumably no file system exists.

Alternatively, the file system on which you were trying to run is corrupted, or simply missing */etc/init*. Try reinstalling the appropriate file system or installing a version of *init*.

system selects incorrect root device

That is, you try to boot the system single user with "B/2" or "B xxS" but do not get the root file system in the expected location. This is most likely caused by your having many disks available more suited to be a root file system than the one you wanted. For example, if you have a "up" disk and an "hk" disk and install the system on the "hk", then try and boot the system to single-user mode, the heuristic used by the generic system to select the root file system will choose the "up" disk. The following list gives, in descending order, those disks thought most suitable to be a root file system: "hp", "up", "ra", "rb", "rl", "hk" (the position of "rl" is subject to argument). To get the root device you want you must boot using "B/3" or "B ANY", then supply the root device at the prompt.

system crashes during autoconfiguration

This is almost always caused by an unsupported UNIBUS device being present at a location where a supported device was expected. You must disable the device in some way, either by pulling it off the bus, or by moving the location of the console status register (consult Appendix A for a complete list of UNIBUS csr's used in the generic system).

system does not find device(s)

The UNIBUS device is not at a standard location. Consult the list of control status register addresses in Appendix A, or wait to configure a system to your hardware.

Alternatively, certain devices are difficult to locate during autoconfiguration. A classic example is the TS11 tape drive which does not autoconfigure properly if it is rewinding when the system is rebooted. Tape drives should configure properly if they are off-line, or are not performing a tape movement. Disks which are dual-ported should autoconfigure properly if the drive is not being simultaneously accessed through the alternate port.

Building console cassettes

This sections describes common problems encountered while constructing a console bootstrap cassette.

system crashes

You are trying to build a cassette for an 11/750. On an 11/750 the system is booted by using a bootstrap prom and sector 0 of the root file system. Refer to section 2.1.5 or *tu* (4) for the appropriate reprimand.

system hangs

You are using an MRSP prom on an 11/750 and think you can ignore the instructions in this document. The problem here is that the generic system only supports the MRSP prom on an 11/730. Using it on an 11/750 requires a special system configuration; consult *tu* (4) for more information.
